A MEDICAL JOURNAL CONTAINING

HE OFFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ AT
THE ANNUAL SESSION, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY
GEORGE H. SIMMONS, LL.D., M.D.

VOLUME LXII : : : : : JANUARY—JUNE, 1914

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1913-1914

GENERAL OFFICERS

PRESIDENT—JOHN A. WITHERSPOON	Nashville, Tenn.
PRESIDENT-ELECT—VICTOR C. VAUGHAN	Ann Arbor, Mich.
FIRST VICE-PRESIDENT—WALT P. CONAWAY	Atlantic City, N. J.
SECOND VICE-PRESIDENT—FRANK C. TODD	Minneapolis, Minn.
THIRD VICE-PRESIDENT—LILLIAN H. SOUTH	Bowling Green, Ky.
FOURTH VICE-PRESIDENT—SOL. G. KAHN	Salt Lake City, Utah
EDITOR AND GENERAL MANAGER—GEORGE H. SIMMONS	535 N. Dearborn St., Chicago
SECRETARY—ALEXANDER R. CRAIG	535 N. Dearborn St., Chicago
TREASURER—WILLIAM ALLEN PUSEY	Chicago

BOARD OF TRUSTEES

Philip Marvel	Atlantic City, 1914
Philip Mills Jones	San Francisco, 1914
W. T. Sarles	Sparta, Wis., 1914
M. L. Harris, Secretary	Chicago, 1915
Thomas McDavitt	St. Paul, Minn., 1915
W. T. Councilman, Chairman	Boston, 1915
W. W. Grant	Denver, 1916
Frank J. Lutz	St. Louis, 1916
Oscar Dowling	Shreveport, La., 1916

JUDICIAL COUNCIL

Alexander Lambert, Chairman	New York City, 1914
James E. Moore	Minneapolis, 1915
Hubert Work	Pueblo, Colo., 1916
George W. Guthrie	Wilkes-Barre, Pa., 1917
A. B. Cooke	Los Angeles, Cal., 1918
Alexander R. Craig, Secretary	535 N. Dearborn St., Chicago

COUNCIL ON HEALTH AND PUBLIC INSTRUCTION

H. M. Bracken	Minneapolis, 1914
W. C. Woodward	Washington, D. C., 1915
H. B. Favill, Chairman	Chicago, 1916
Walter B. Cannon	Boston, 1917
W. S. Rankin	Raleigh, N. C., 1918
Frederick R. Green, Secretary	535 N. Dearborn St., Chicago

COUNCIL ON MEDICAL EDUCATION

Arthur D. Bevan, Chairman	Chicago, 1914
George Dock	St. Louis, 1915
W. D. Haggard	Nashville, Tenn., 1916
James W. Holland	Philadelphia, 1917
H. D. Arnold	Boston, 1918
N. P. Colwell, Secretary	535 N. Dearborn St., Chicago

COUNCIL ON PHARMACY AND CHEMISTRY

L. F. Kebler	Washington, D. C., 1914
John Howland	Baltimore, 1914
Henry Kraemer	Philadelphia, 1914
F. G. Novy	Ann Arbor, Mich., 1915
George H. Simmons, Chairman	Chicago, 1915
H. W. Wiley	Washington, D. C., 1915
O. T. Osborne	New Haven, Conn., 1916
Torald Sollmann	Cleveland, Ohio, 1916
M. I. Wilbert	Washington, D. C., 1916
Reid Hunt	Boston, 1917
J. H. Long	Chicago, 1917
Julius Stieglitz	Chicago, 1917
J. A. Capps	Chicago, 1918
David L. Edsall	Boston, 1918
R. A. Hatcher	New York City, 1918
W. A. Puckner, Secretary	535 N. Dearborn St., Chicago

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Charles L. Greene, St. Paul; Vice-Chairman, John B. Elliott, Jr., New Orleans; Secretary, Roger S. Morris, Clifton Springs, N. Y.

SURGERY—Chairman, Charles H. Frazier, Philadelphia; Vice-Chairman, J. E. Thompson, Galveston, Tex.; Secretary, E. S. Judd, Rochester, Minn.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY—Chairman, E. Gustav Zinke, Cincinnati; Vice-Chairman, A. E. Benjamin, Minneapolis; Secretary, Brooke M. Anspach, 119 S. 20th St., Philadelphia.

OPHTHALMOLOGY—Chairman, Frank C. Todd, Minneapolis; Vice-Chairman, William Zentmayer, Philadelphia; Secretary, George S. Derby, 7 Hereford St., Boston.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY—Chairman, Burt R. Shurly, Detroit; Vice-Chairman, L. W. Dean, Iowa City, Ia.; Secretary, F. P. Emerson, 520 Commonwealth Ave., Boston.

DISEASES OF CHILDREN—Chairman, F. S. Churchill, Chicago; Vice-Chairman, L. R. DeBuys, New Orleans; Secretary, F. P. Gengenbach, 1434 Glenarm St., Denver.

PHARMACOLOGY AND THERAPEUTICS—Chairman, J. F. Anderson, Washington, D. C.; Vice-Chairman, R. A. Hatcher, New York; Secretary, M. I. Wilbert, 25th and E Sts., N. W. Washington, D. C.

PATHOLOGY AND PHYSIOLOGY—Chairman, William Ophüls, San Francisco; Vice-Chairman, L. B. Wilson, Rochester, Minn.; Secretary, A. J. Carlson, University of Chicago, Chicago.

STOMATOLOGY—Chairman, William C. Fisher, New York; Vice-Chairman, F. B. Moorehead, Chicago; Secretary, Eugene S. Talbot, 31 N. State St., Chicago.

NERVOUS AND MENTAL DISEASES—Chairman, W. W. Graves, St. Louis; Vice-Chairman, C. D. Camp, Ann Arbor, Mich.; Secretary, G. A. Moleen, Mack Bldg., Denver.

DERMATOLOGY—Chairman, Richard L. Sutton, Kansas City, Mo.; Vice-Chairman, J. B. Kessler, Iowa City, Ia.; Secretary, Howard Fox, 616 Madison Ave., New York.

PREVENTIVE MEDICINE AND PUBLIC HEALTH—Chairman, M. P. Ravenel, Madison, Wis; Vice-Chairman, W. C. Rucker, Washington, D. C.: Secretary, C. Hampson Jones, 2529 St. Paul St., Baltimore.

GENITO-URINARY DISEASES—Chairman, Arthur L. Chute, Boston; Vice-Chairman, Granville MacGowan, Los Angeles; Secretary, Louis E. Schmidt, 5 S. Wabash Ave., Chicago.

HOSPITALS—Chairman, L. B. Baldwin, Minneapolis; Secretary, John A. Hornsby, 6 N. Michigan Ave., Chicago.

ORTHOPEDIC SURGERY — Chairman, Leonard W. Ely, San Francisco; Vice-Chairman, Nathaniel Allison, St. Louis; Secretary, Emil S. Geist, 614 Syndicate Bldg., Minneapolis.

EARLY USE OF THE ROENTGEN RAY IN THE STUDY OF THE ALIMENTARY CANAL*

W. B. CANNON, M.D.
BOSTON

My reasons for preparing the present paper were various. First of all, I must confess to never having carefully looked up the historical sequence of early literature on the technic of applying the Roentgen rays to the alimentary canal, and I wished to do that. Second, an account of the first Roentgen-ray experiments on the digestive tract performed in the Harvard Physiological Laboratory has never been written, and that, I thought, might be interesting to members of the American Roentgen Ray Society. Finally, my activities during the past few years have not been concerned with use of the Roentgen rays, and when asked to speak here, I had nothing else to bring than the story of these early observations.

When in December, 1895, Roentgen[1] announced the discovery of a "new kind of rays," he pointed out that the salts of metals, either solid or in solution, behaved generally as the metals themselves, in obstructing the passage of his new rays.[1] Within two months, in February, 1896, the possibility of rendering hollow organs visible by injecting them with salts was demonstrated by Dutto,[2] who filled arteries with plaster of Paris and then photographed them. A month later, in March, 1896, Becher[3] published a roentgenogram of a dead guinea-pig in which he had distended the stomach and a loop of the small intestine with lead subacetate; the stomach shadow was quite indistinct, but the intestinal loop showed clearly. In April, 1896, Wegele[4] suggested that it would be possible to introduce a spiral electrode into the human stomach and by roentgenographing it to determine the limits of the greater curvature; it was not until a year later, however, that the suggestion was carried out by Lindemann,[5] who introduced a soft stomach-tube enclosing a fine copper wire and obtained a roentgenogram of the wire as it lay along the lower gastric border. Meanwhile Hemmeter,[6] having noted Becher's roentgenogram of the dead guinea-pig with stomach and intestine made visible by injected lead salts, and having recently devised an intragastric bag, proposed that the bag be pushed into the stomach and filled with a solution of lead acetate to render the shape of the stomach capable of being roentgenographed. I am not aware that Hemmeter's proposal was ever put to practical test.

In the fall of 1896, when I was a first-year student in the Harvard Medical School, and Mr. Albert Moser, a Cambridge acquaintance, was a second-year student, we went to Prof. *H. P.* Bowditch and asked for an opportunity to undertake a physiologic investigation. He suggested that we test by means of the newly discovered Roentgen rays the Kronecker-Meltzer view of deglutition—namely, that substances when swallowed are shot down the esophagus by pressure developed in the mouth, and are not pushed down by a peristaltic wave. A small static machine and some simple tubes were secured, and we set to work. Our first observation was made on Dec. 9, 1896, when we watched globular pearl buttons pass down the esophagus of a dog. On December 14, we repeated the observations on a rooster whose neck was *kept straight by fastening the head and body in fixed* positions.

That substances vary in their opacity to the Roentgen ray in accordance with their molecular weight was then common knowledge. Barium and bismuth were selected from among the heavy metals, and barium sulphate and bismuth subnitrate were chosen as salts which, because practically insoluble, would serve our purposes. Since bismuth subnitrate was a pharmacopeial preparation we determined first to use that.[7] On Dec. 16, 1896, we gave a frog a gelatin capsule filled with this bismuth salt, and after seeing clearly the shadow of the substance in the frog's stomach, we repeated, the next day, December 17, the use of the salt in a capsule to show deglutition in the dog. When the swallowed capsules were dissolved, the bismuth subnitrate was liberated; and in my notes I find the remark that thus a dark roundish area was produced as a stomach shadow. Then we procured a goose and made for it a box so arranged that the long neck reached up through the cover. A high cardboard collar was then attached to the top of the box in such a way that it could be closed in front when surrounding the goose's neck. Thus the goose, with the appearance of using the most stylish neckwear, presented to the fluorescent screen a very satisfactory extent of esophagus. At the meeting of the American Physiological Society in Boston, Dec. 29, 1896, the phenomena of deglutition as exhibited by the goose when swallowing capsules containing bismuth subnitrate was informally demonstrated to the members by means of the Roentgen rays. This was, I think, the first public demonstration of movements of the alimentary tract by use of the new method.

---

* Read at the fourteenth annual meeting of the American Roentgen Ray Society, Boston, Oct. 2, 1913.

[7] Later I showed that barium sulphate mixed with the food was quite as satisfactory as bismuth subnitrate. Cannon, W. B.: Am. Jour Physiol., 1904, xii, 388.

It was not until Jan. 9, 1897, that we employed bismuth subnitrate mixed with the food (in this case a bread mush) to render the swallowed mass visible. And in order to test the rate at which substances with different consistencies move along the esophagus, we added more or less water to the mush, thus varying its physical state from a rather stiff mass to a very soft, nearly fluid mixture. Various observations of this nature were made on the goose in January, February and March, 1897. On April 3, 1897, we began using the same mush-bismuth bolus, and also meat with bismuth subnitrate adherent, in a study of swallowing in the cat, and as the mixture of bismuth subnitrate and food accumulated in the stomach, that organ was outlined by a dark shadow. On April 3, and in observations on several days thereafter, the gastric contents became visible as the cats swallowed more and more of the mixture, but no movements of the wall were seen. Finally, on April 23, 1897, a cat was fed bread soaked in warm water, and mixed with bismuth subnitrate; about an hour and a half later peristaltic waves were clearly seen passing over the organ. Following is a transcript of my notes taken at the time:

> "A constriction seemed to start at *A* (*A* referred to a drawing and indicated the middle of the stomach), making a clear line there and forcing a black round mass into the region of *B* (the pyloric region). The constriction passed downward from *A* to *C* (the pylorus), but as the pylorus did not give way the contents of the stomach at *B* (the pyloric region) were forced back through the constricted ring. . . . As soon as the constriction had passed from *A* to *C*, it began again at *A* and the food was thus squirted through the narrow orifice caused by the constriction. This process continued a number of times, the food in region *D* (the cardiac region) apparently not at all involved in the movement." Forty minutes later the gastric movements were seen going on in the same manner.

The foregoing description records the first observation of peristaltic waves passing over the stomach contents, as seen by the Roentgen rays when the ingested food was mixed with a bismuth salt. Later observations refined the description—thus it was soon found that several waves are present at the same time—but the main facts, that the waves start at about the middle of the stomach, and that, because the pylorus does not open at the approach of every wave, these moving constrictions churn the food in the pyloric end—these facts were noted with this new method at first glance.

At a meeting of the American Physiological Society in Washington, May 4, 5 and 6, 1897, a preliminary report of these observations was presented by Professor Bowditch, and the summary of the report was published a month later.[8] A part of the summary was as follows:

> "For this purpose (studying the esophageal and gastric movements by means of Roentgen-ray shadows) moist bread, meat, mush or viscid fluids were mixed with bismuth subnitrate. Food thus prepared is visible during the process of deglutition, and, if given in sufficient quantities, serves to outline the stomach and to render its peristaltic movements visible." Then followed an account of the results which had been obtained in observing deglutition in different animals, and also gastric peristalsis.

This was not the first published account of the use of bismuth subnitrate to make visible the alimentary tract. About two months before (April 20, 1897) Rumpel[9] published the report of rendering a pathologically dilated esophagus visible by pouring into it 300 c.c. of a 5 per cent. suspension of bismuth subnitrate. The account of work done in the Harvard laboratory which was published June 11, 1897, was, however, so far as I have been able to learn, the first record of the use of a heavy salt mixed with the food—the method now employed—to render visible by means of the Roentgen rays the movements of the alimentary tract and the effects of these movements on the contents.

At the meeting of the Société de Biologie in Paris, June 12, 1897, about five weeks after the meeting of the American Physiological Society in Washington, Roux and Balthazard[10] reported observations on gastric peristalsis in the frog, studied by means of the Roentgen rays. They also used food mixed with bismuth subnitrate. These observations were followed by others on the stomach movements of the dog and of man (July 24, 1897).[10] Roux and Balthazard[11] gave to their human subject 15 or 20 gm. of bismuth subnitrate suspended in 100 c.c. of water. They were the first investigators to use the method to examine peristalsis of the human stomach, but they succeeded in seeing only the lower part of the greater curvature.

The work on cats was continued in Harvard laboratory during the summer and fall of 1897. The results of this labor were reported at the meeting of the American Physiological Society, Dec. 28, 1897, and published in the *Proceedings*, April 1, 1898.[12] The completed work on the movements of the stomach appeared in May, 1898.[13] Later accounts of the movements of the small and large intestines and of the rate of passage of different foodstuffs through the alimentary canal, all studied by the same method, were published from the Harvard laboratory,[14] and these papers, together with the paper on deglutition, finished the non-experimental, purely observational studies.

In the work on deglutition Mr. Moser and I, in the fall of 1897, made observations on a girl aged 7 and saw clearly capsules containing bismuth subnitrate, boluses of bread and milk mush mixed with the salt, and also a suspension of the salt in water, passing down the esophagus.[15]

In 1898 and in 1899 Dr. Francis H. Williams and I made some studies on the changes in shape of the human stomach as it empties. A boy aged 10 and his sister aged 7 were the subjects of our examinations. The boy was fed a pint of bread and milk to which 30 gm. of bismuth subnitrate had been added; his sister received a smaller amount. Tracings were made on transparent paper laid over the fluorescent surface. These tracings show clearly the vertical position of the stomach now so well known, and a gradual shortening of the organ as it discharges its contents. These records were not published at once, but appeared in 1903.[16]

A year after this publication by Dr. Williams, Rieder[17] reported his thorough study of the alimentary canal in man. The method used by Rieder was that which had been used many times before. Rieder himself definitely stated in his more extended paper in 1905 that his use of bismuth subnitrate mixed with the food, as a means of rendering opaque to the Roentgen rays the contents of the alimentary canal, was not new, and he presented a review of previous work in which this method had been employed.

In spite of Rieder's disavowal of the introduction of any new principle into methods of gastro-intestinal examination, it is not uncommon nowadays to find in clinical literature, especially in Germany, the use of a heavy salt mixed with the food to make Roentgen-ray shadows, referred to as "Rieder's method."[18] The assertion made by those who credit Rieder with the method is that he was first to demonstrate that giving large amounts of bismuth is harmless for the human organism (Albers-Schönberg[18] and Krause and Schilling[18]). It is doubtful if bismuth subnitrate is as assuredly harmless as was assumed in the early days.[19] Be that as it may, Groedel[18] has pointed out that Rieder's use of massive doses of bismuth subnitrate (from 40 to 50 gm.) rested in fact on the long experience of internists who, following Kussmaul, had given for gastric ulcer large doses—doses which would result in as much as 60 gm. being in the digestive tract at one time. This tendency to ascribe to Rieder the shadow method of studying the alimentary canal is not, however, confined to Germany. A recent article[20] in this country on Roentgen technic begins thus:

> The fundamental principle of Roentgen-ray examinations of the stomach and intestine is the visualization of their outline by filling them with substances opaque to the ray, a principle which we owe to Rieder of Munich who, in 1904, first used bismuth subnitrate for the purpose.

As already stated, Rieder himself clearly disclaims any such credit as is thus given to him.

The evolution of the Roentgen-ray shadow method of examining the digestive tract has gone forward with such great strides in these later years—with the manufacture of powerful electric generators and durable tubes and with the application of the method to all manner of practical problems of diagnosis, such as constipation, and obstruction, and tumors, and ptosis and what not else—that the small beginnings which I have recounted here seem trivial enough. This historical review which I have tried to present may, however, serve to show that the use of Roentgen-ray shadows of gastro-intestinal contents, to determine normal and pathologic motions of the alimentary tract, has been a gradual development. The interdependence of ideas in any such development is so complex that it is quite possible that the method now employed originated in fact in the statement contained in Roentgen's first announcement, that the salts of heavy metals are as opaque to the rays as the metals themselves. The injection of blood-vessels and intestinal loops with salts showed almost at once that any hollow organ could be made, in the presence of Roentgen rays, to manifest its contours. The mixing of heavy salts with the food to render gastro-intestinal movements visible was, so far as I have been able to learn, first used in the Laboratory of Physiology in the Harvard Medical School; but the method contained, to my mind, no principle which had not been utilized before. Under these circumstances there is little warrant for any man to claim for himself or for any other the credit of inventing the method now used everywhere in Roentgen examinations of the alimentary canal.

A STATISTICAL STUDY OF PROGNOSIS IN INSANITY

A. J. ROSANOFF, M.D.
KINGS PARK, N. Y.

The introduction of Kraepelin's classification has been of benefit, but not unmixed with drawbacks—none the less real for being unnecessary—among which not the least regrettable has been the growth of a tendency to neglect the consideration of prognosis, as based on the special data of cases in hand, seemingly owing to an assumption that the prognosis is fully implied in the diagnosis. In other words, the improvement of the criteria in general prognosis has been somewhat at the expense of individual prognosis.

To this tendency there would be no objection if the criteria as applied to general prognosis were trustworthy in every case; but this, in fact, is not true and he who is satisfied with saying, "This is a case of dementia praecox, it will, therefore, end in deterioration," or "This is a case of manic-depressive insanity, it will, therefore, end in recovery, but there are likely to be recurrences," is making a forecast that is neither reliable nor so full and detailed as desirable and, under some conditions, possible; for, on the one hand, there is possibility of error in his prediction—even assuming correctness of diagnosis—and, on the other hand, he has yet failed to offer a judgment on many important points. How rapid, how marked and disabling a deterioration may be expected in the case of dementia praecox? Is the course to be steadily progressive or, perhaps, interrupted by remissions? In the case of manic-depressive insanity, how soon is the recovery to be expected and when the recurrences? In either case, to what extent, if any, may the future course be influenced by environmental conditions?

Perhaps in the process of assimilating Kraepelin's teaching it has been but natural for us to endeavor first to grasp its more fundamental points, to seek a view of its general outline; but it would seem that we are now past the stage of this preliminary work and are far enough advanced to begin adding the "grain of salt" which must be taken with every generalization.

That the matter of prognosis deserves more intensive special study than it has hitherto received needs hardly to be stated, for no issue urges itself more prominently on the clinical psychiatrist in his daily work; but there are two items of advantage that may be gained from the systematic practice of prognosis which are perhaps not generally realized. The first of these consists in a corrective control that would become available for clinical work and judgments; under ordinary conditions, attention being almost wholly given to diagnosis, an unexpected outcome in a given case elicits but the explanation that "exceptions are not uncommon." A more specific explanation, derived from the facts in the case, would probably be sought if an individual prognosis had been rendered. The second item of advantage consists in the development of sound and crucial criticism of therapeutic procedures that would follow the prognosis. Any case in which improvement followed the use of hydrotherapy, psychanalysis, reeducation, or what not, would be of greater value were a thoroughly discussed prognosis previously rendered than when, as is usual, without hesitation or compunction, the improvement is directly attributed to the treatment.

Hitherto individual prognosis has been an art rather than a science, and one, moreover, practiced at times

TABLE 1.—OUTCOME, AS FAR AS KNOWN ON SEPT. 30, 1913, OF ALL FIRST ADMISSIONS FOR THE YEAR ENDING SEPT 30, 1908

Clinical Groups	No. of Cases			Deported		Repatriated		Died		Discharged		At Hospital

All groups (including four not insane)	612	130	21.2	85	13.7	16	2.6

*Four patients on first admission were discharged as not insane quite independently of Kraepelin's contributions. It may be hoped, however, that careful records of data of experience will aid in building up also a science of prognosis, when its practice will be more accurate and more general. But for the present, if the procedure is to be in a natural way from the known to the unknown, it would seem wisest not to attempt a discussion of the rather meager data of individual prognosis—a discussion which would be perforce largely conjectural—but rather to work toward improving our methods of recording clinical experiences until a system of statistics is developed which will faithfully exhibit both the strength and the weakness of present-day general prognosis.

At the last annual meeting of the American Medico-Psychological Association a paper entitled "Statistical Studies of the Insane" was read by Dr. James V. May, the medical member of the New York State Hospital Commission. Among other criticisms of state hospital statistics the paper contains the following:

> The recovery-rate has been estimated as based on the number admitted for the year, the average daily population, the whole number treated, the number discharged and the rate per thousand or ten thousand of the admissions, etc. All these methods are, to say the least, unreliable if not absolutely misleading. The total number of recoveries includes those occurring in the whole population under treatment, representing (in large part) the accumulation of years in the form of various psychoses from which no recovery can possibly be expected, such as *epileptics, seniles, imbeciles and* the terminal stages at various other conditions. The recoveries from the total population have little if any real relation to the number admitted during the year. It would be highly desirable if from a given thousand or ten thousand consecutive admissions accurate and definite reports could be obtained showing how many are discharged improved or recovered, how many die, and what percentage becomes permanently resident in our chronic wards. Only such statistics can accurately determine the real recovery-rate or give us any definite idea as to the ultimate disposition of the patients admitted.

Following the suggestion contained in the preceding quotation an investigation has been made of the outcome, as far as known at present (Sept. 30, 1913), of all cases of first admission to the Kings Park State Hospital for the year ending Sept. 30, 1908. The data resulting from this investigation are presented in statistical form in Tables 1 to 5.

TABLE 4.—SUBSEQUENT COURSE OF PATIENTS DISCHARGED INTO THE CUSTODY OF SELF, RELATIVES OR FRIENDS*

Some items in the tables require explanation.

Under the heading "Deported" are included patients returned to their native countries by federal authorities under the federal law pertaining to the exclusion of insane or defective aliens.

Under the heading "Repatriated" are included immigrants not deportable under the federal law but returned to their native countries or states at their own or their friends' request, for the most part through the agency of the state bureau of deportation. The further course of cases following deportation or repatriation is generally unknown.

Under the heading "Discharged" are included patients who have been discharged following escape from the hospital or into the custody of self, relatives or friends, but not patients who have been deported, repatriated or transferred to other institutions for the insane in this state.

Under the heading "At Hospital" are included patients who from the time of first admission have either continuously resided at this hospital, or in part at this hospital and in part at some other hospital in this state to which they may have been transferred.

If, following transfer to another hospital, a patient has been deported, repatriated, has died or has been discharged into the custody of self, relatives or friends, this has been so entered in the table, just as has been done in the event of such termination of treatment during residence at this hospital.

In Table 2 the average length of hospital residence includes residence both at this hospital and at other hospitals to which the patient may have been transferred, but in each case only the residence following first admission is taken into account.

In Table 4, under the heading "Not Known to Have Been Readmitted," some cases have perforce been entered for want of better information. Although the statistician of the State Hospital Commission has kindly rendered assistance in the collection of these data by going over the records kept at its office at Albany, there is no doubt that some instances of readmission to institutions in this state have been overlooked owing to the patients being recommitted under changed names or for other reasons. Naturally information concerning readmission to institutions in other states or countries is still more imperfect. It will be judged, then, that the percentages of readmissions during the period under consideration, as shown in the table, must be to some unknown but probably considerable extent understated.

In all of the tables the diagnoses given are not necessarily those originally made, but are those finally decided on, possibly following revision at any time in the course of observation or treatment or at the time of discharge or following death and post-mortem examination. In this connection attention is called particularly to the groups allied to dementia praecox and allied to manic-depressive insanity. In these groups are placed patients who present atypical features of any kind, among these being unexpected recovery or unexpected deterioration or chronicity. It need hardly be added that these groups ought to be considered not independently but in connection with the "straight" groups of dementia praecox and manic-depressive insanity.

SUMMARY

The main facts exhibited in the tables may be summarized as follows:

1. At the end of five years, one-fourth of all first admissions have died, a little over one-third have been discharged, and about one-third are still in the state institutions. These results are, however, very unequally distributed among the various clinical groups, as would indeed be expected.

2. Taking into consideration only the more important clincal groups, it will be seen that death is the typical termination for patients with senile psychoses, general paresis and cerebral arteriosclerosis; discharge into the custody of self, relatives or friends for alcoholic psychoses, psychoses allied to dementia praecox and manic-depressive and allied psychoses and continued residence at the hospital for dementia praecox and paranoiac conditions.

3. Aside from the patients that survive and remain as prolonged institution residents, the termination of treatment in the average case has been before the expiration of the first year of hospital residence, namely, at the end of ten months, eleven days.

4. Nearly one-half of the patients in the group allied to dementia praecox have been discharged as recovered, many of those being placed in that group instead of the "straight" group of dementia praecox for no other reason than that of their eventual recovery; moreover, a percentage of these patients higher than the average find their place at the end of five years under the heading "Not Known to Have Been Readmitted" (Table 4).

5. Four per cent. of the cases in the manic-depressive group and over 17 per cent. of those in the group allied to manic-depressive psychoses are still in the institutions at the end of five years.

6. Of all the patients discharged into the custody of self, relatives or friends nearly 20 per cent., and possibly more, have been readmitted within five years.

7. The distribution of the causes of death is abnormal in comparison with general mortality statistics; of the 153 deaths no less than 112, or 73.2 per cent., are due to but four principal causes—general paresis, bronchopneumonia, pulmonary tuberculosis and acute enterocolitis.

THE INTRANASAL TREATMENT OF DYSMENORRHEA

WITH A REPORT OF NINETY-THREE CASES [*]

EMIL MAYER, M.D.
Attending Laryngologist, Mount Sinai Hospital; Chief of Clinic, Ear and Throat Department, Mount Sinai Hospital Dispensary
NEW YORK

In 1897 Fliess[1] first called attention to the hitherto unknown and remarkable results obtained by treatment of the nose for the relief of dysmenorrhea and labor pains. In the same brochure he presented a series of facts tending to prove the existence of a *periodicity* in human life stated to be twenty-eight days in the female and twenty-three days in the male.

The relationship between the nose and uterine organs was limited, according to Fliess, to certain points in the nasal mucosa which he termed the "genital spots." These are the tuberculum septi and the anterior portion of the inferior turbinate in either side of the nose. At menstruation these swell, bleed easily, are sensitive to the touch of a probe and are slightly cyanotic. During labor Fliess noted a swelling of the erectile tissue of the nose at each uterine contraction.

---

[*] Owing to lack of space this article is abbreviated in The Journal by the omission of ninety-three case-reports. The complete article appears in the author's reprints, a copy of which will be sent by him on request.

[*] Read before the meeting of the American Academy of Ophthalmology and Otolaryngology at Chattanooga, Tenn., Oct. 26, 1913.

[1] Fliess: The Relation of the Nose and Female Genitalia, Leipsic, Vienna 1897.

His first experiments were with cocain. During an attack of dysmenorrhea applications of a 20 per cent. solution of cocain were applied to the genital spots; the pains in the back and abdomen ceased after from five to eight minutes and did not return until the effect of the cocain wore off. If only turbinates were touched the headache ceased but not the abdominal pain. If only one side was treated, the pain on the opposite side of the abdomen was relieved. I[2] have since obtained similar results with epinephrin, and Fliess and Kuttner[3] have obtained similar results.

Fliess then endeavored to secure permanent effects and applications of trichloracetic acid, the galvanocautery and bipolar electricity were made to the genital spots with entire success as the succeeding menstruations were painless. His best and most lasting results were obtained by the abolition of the sensitive spots by means of bipolar electrolysins of from 5 to 8 milliamperes.

Fliess naturally presented his own theories as to the explanation of this remarkable relationship, and these have been combated by many subsequent writers, the most recent of whom, Seifert[4] concludes as follows:

> 1. There are many indications pointing to a direct relation between the nose and the sexual organs; the nerve path is unknown.
>
> 2. General circulatory and mechanical conditions have a greater or lesser modifying influence on the nose as a result of sexual conditions and functions.
>
> 3. Many pathologic conditions of menstruation, etc., coexist with a genuine nasal reflex neurosis or nasal hypertrophy with its results.
>
> 4. Uterine influence through nasal conditions may be largely explained by suggestion, by cocain euphoria, greater in certain individuals than in others, by relief of a nasal reflex neurosis, and through the restoration of the general health as a result of restored nasal respiration and relief of nasal congestion.

It must be added that Seifert's experience with the treatment of dysmenorrhea is so slight and inconsequential that his conclusions and theories lack the weight that a greater experience would give. The subject has aroused intense interest on the part of gynecologists as well as rhinologists, as may be noted by the fact that the article referred to by Seifert[4] contains references to 296 articles written on the relationship between the nose and the sexual organs.

Although the nasal treatment for dysmenorrhea had been followed by me in some desultory cases with more or less success, it was not until the fall of 1910, three years ago, that a careful and systematic study of each case so treated was begun. In conjunction with Dr. Joseph Brettauer, of this city, and other noted gynecologists, the absence of uterine disease as a causal factor was ascertained. In some instances all the well-known methods of surgical intervention, dilatation, curettage, etc., had been unsuccessful. Concise histories were taken as to the conditions existing whether premenstrual, during menstruation or postmenstrual; by far the greater number of patients having premenstrual headaches and nausea from one to two weeks before the period to be followed by abdominal pains during the first two days often of so severe a nature as to compel them to go to bed, losing at least two days each month. Some of them had a fortnight of reasonable comfort, when their sufferings began again.

The date of last menstruation and probable date of the next was ascertained and the treatment in the majority of instances was given between these two. The nasal examination revealed in a few instances marked stenosis from deflected septa, hypertrophy of middle turbinates, etc., and enchondroses of the septum. All of these patients recovered so completely and permanently as to permit a favorable prognosis in each instance.

In the greater number of cases, however, there was *no stenosis whatsoever*, but there was noted a decided tumefaction and engorgement about these "genital spots," and in these the likelihood of benefit to be obtained was believed to be apparent.

In some of the cases the pains existed only at the time of menstruation. These patients received local applications of cocain to the sensitive spots only during the first or second day of menstruation.

The relief occasioned then was often truly wonderful, and the bald recital of pain, treatment and relief tells so little. When we recall the extreme pallor of one of these sufferers as she slowly dragged her way to the office for treatment, her firmly compressed lips and utter weariness, and then within a few minutes after a local application to her nose how her color came back, her breathing was free and she went about her duties instead of to bed as usual, we feel that we have earned her gratitude.

We found that this treatment had to be repeated each month and therefore ceased the cocain experimentation and used the galvanocautery or the trichloracetic acid. The results obtained by the latter were so permanent, and the treatment was so free from the danger of forming synechiae, that in the latter cases in this series all patients were treated with the trichloracetic acid. A mild solution of cocain was applied just before the use of the acid. The slough that forms disappears in about five days, and another application may be made; four applications were made between periods. The patient was then requested to report the results of her next menstruation. If entirely favorable two more reports were requested, and if these remained as favorable nothing further was done.

In those cases in which relief was slight or the results not at all favorable, four more applications were made between menstruations, and if no benefit was obtained the result was marked "no benefit."

While reports of these cases are given later, the histories which follow are illustrative:

CASE 2.—A. K., aged 25, single; Oct. 5, 1910. Menstruation was always painful; on the first two days the patient was compelled to go to bed and take full doses of codein. Two large enchondroses of the septum were removed, and the galvanocautery was applied to sensitive spots. Three years later the patient reports that she has never had menstrual *pain* since.

CASE 3.—C. S., aged 24, single; Oct. 12, 1910. There were severe headache and nausea one week before each menstruation, and severe bearing-down pains the first two days with nausea and headache. The patient was incapacitated from work and compelled to go to bed at least two days each month. There was enchondrosis of septum, and both inferior turbinates were swollen. Operation and subsequent treatment cured this patient.

CASE 13.—M. H., aged 28, married eight years; no children; October, 1911. The patient had excruciating pains immediately before and until menstruation began, and had been operated on four times without obtaining relief. There was deflection of the cartilaginous and bony nasal septum. Treatment *was given by resection and the galvanocautery.* The patient reported six months later that she had menstruated regularly and painlessly. Six months later she reported herself four months pregnant and subsequently brought her baby, a fine healthy child, to my office.

[2] Mayer: Centralbl. f. Laryngol., 1902, p. 243.
[3] Fliess and Kuttner: Centralbl. f. Gynäk., 1908, p. 981.
[4] Seifert: Ztschr. f. Laryngol., Rhinol. u. i. Grenzgeb., 1912, v, 431.

CASE 29.—F. G., aged 31, single; January, 1911. For the past two years severe menstrual pains, on the first day only, incapacitated the patient. She was unwell at the time, and cocain applied stopped her pain. Three months later pain recurred. Cocain and trichloracetic acid were applied, and there was no recurrence of pain.

CASE 74.—F. L., aged 41, married; November, 1912. The patient had severe headaches four days before each menstruation with nausea, and relief was *obtained only by the hypodermic* injection of morphin. Eight applications of trichloracetic acid to sensitive spots were made between menstruations. The patient reported complete cessation of headaches since the last treatment.

The case-reports which follow form in part the basis of two articles by Brettauer, in the second[5] of which he says that after communicating with all patients treated within the last three years, he finds that over one-half were afforded immediate relief, permanent relief in over one-third, so that doubt as to the value of the treatment is impossible. The patients were all young women, married and single, for whom all the recognized means for the relief of dysmenorrhea had been previously employed and whose pelvic organs presented no organic lesions. One group stands out prominently; those characterized by premenstrual headache, nausea and colic at onset of flow. This symptom-complex was completely relieved. Brettauer considers this treatment of great value and one which should be resorted to in all cases of dysmenorrhea in which pelvic disease is absent.

In all of the ninety-three cases, the greatest care was taken to eliminate the possibility of suggestion, and no promises were ever made. On the contrary, it was briefly explained that some had been benefited and it was hoped that they also might obtain relief; a number of the patients were treated in the dispensary—a place where none could be accused of extended conversation or statements. Nor can any weight be given to the theory of cocain euphoria thus blunting the patient's judgment, for by far the greater number received but little cocain and none at all at the time when their sufferings were due.

That a measure of relief is obtainable by the relief of nasal congestion is very apparent in that every one with pathologic conditions in the nose was permanently cured after their removal, but the manner in which this is occasioned is still an open question.

Of the ninety-three patients whose histories are here briefly presented no report was received from twelve, leaving a total of eighty-one cases reported on. Of these no relief was obtained in nineteen, fourteen were improved and forty-eight were cured—a cure of 60 per cent. of the cases treated with benefit to a total of 75 per cent. Three were treated because of amenorrhea lasting for from three to twelve months, and in each the flow became regular. Four became pregnant, two for the first time. One-half of the number were married. These results are given from the reports made by the patients after treatment.

CONCLUSIONS

1. Permanent relief is obtainable by intranasal treatment of from 50 to 75 per cent of the cases.

2. Trichloracetic acid applied to the genital spots four times at intervals between menstrual periods is usually sufficient to obtain lasting results.

3. It affords an additional field of usefulness to our therapeutics.

These patients were from every walk in life. Only the bare facts of the cure of a large number of these patients are given; but we should bear in mind that all of these women suffered inordinately, for most women accept some pain at menstruation as a matter of course, and it is only after the suffering becomes unbearable that the physician is consulted. Therefore their relief without drugs, operation and uterine treatment by a few applications to the nose adds materially to their comfort and the joy of living.

40 East Forty-First Street.

PELLAGRA

A SUMMARY OF THE FIRST PROGRESS REPORT OF THE THOMPSON-MCFADDEN PELLAGRA COMMISSION *

J. F. SILER, M.D.
Captain Medical Corps, U. S. Army
P. E. GARRISON, M.D.
Passed Assistant Surgeon, U. S. Navy
AND
W. J. MACNEAL, M.D.
Assistant Director of Laboratories, New York Post-Graduate Medical School
NEW YORK

Through the instrumentality of Dr. George N. Miller, at that time president of the New York Post-Graduate Medical School, funds were donated by Col. Robert M. Thompson of New York City and Mr. J. H. McFadden of Philadelphia to support a research expedition for the investigation of pellagra in the United States. It was decided that if possible a commission of three would be formed, one member to be designated by the Surgeon-General of the Army, one by the Surgeon-General of the Navy and one by the authorities of the New York Post-Graduate Medical School. Dr. Jonathan Wright, director of laboratories at the medical school, was requested by the school authorities to act in an advisory capacity. The commission was constituted as follows: Captain J. F. Siler, Medical Corps, U. S. Army, representing the Medical Corps of the U. S. Army; Passed-Assistant Surgeon P. E. Garrison, U. S. Navy, representing the Medical Corps of the U. S. Navy, and Dr. W. J. MacNeal, Professor of Bacteriology and Pathology and Assistant Director of Laboratories, New York Post-Graduate Medical School, representing the New York Post-Graduate Medical School.

It was decided that the investigation should be conducted along two lines: first, an epidemiologic study of pellagra in an endemic area of the South; and, second, *biologic, pathologic* and chemical studies in New York City and elsewhere. The epidemiologic studies were undertaken by Passed Assistant Surgeon P. E. Garrison of the U. S. Navy and J. F. Siler, Captain Medical Corps, U. S. Army.

A field headquarters was established in the South early in June, 1912, and the field studies were continued until Oct. 15, 1912. The Bureau of Entomology of the U. S. Department of Agriculture, early in the spring of 1912, detailed Mr. A. H. Jennings and Mr W. V King to investigate the possible etiologic relationship between insects and pellagra. These entomologists were in South Carolina when the field headquarters of the commission was established, and through the courtesy of Dr L O Howard, Chief of the Bureau of Entomology, it was arranged that these investigators and this *commission* should undertake cooperative work in the same territory

[5] Brettauer, Joseph: Further Report of Cases of Dysmenorrhea Relieved by Nasal Treatment, Surg., Gynec. and Obst., 1913, xvii, 381.

* From the Division of Tropical Medicine, Department of the Laboratories, New York Post-Graduate Medical School and Hospital. Read at the Pellagra Meeting at Spartanburg, S. C., Sept. 3, 1913.

Biologic, pathologic and chemical studies were undertaken in the laboratories of bacteriology, pathology and pathologic chemistry of the New York Post Graduate Medical School under the supervision of Dr Jonathan Wright, Director of Laboratories and Dr W J MacNeal, a member of the commission. The researches along these lines were carried out by Dr W J MacNeal, Dr. O. S. Hillman, Dr R M Taylor, Dr A C Myers and Dr. M. S. Fine In order to obtain material for these investigations, selected patients were sent to New York from the endemic area, pathologic material was collected in the field, and other material was supplied to the commission through the courtesy of Dr J. W. Babcock of Columbia, S C Studies of the pathologic material are being undertaken by Dr H Douglas Singer of the Illinois State Psychopathic Institute

Several detailed papers constituting a preliminary or progress report have been published during the past year It is the purpose of this present paper to summarize briefly the observations recorded in these separate reports, to discuss their bearing on the various theories concerning the causation of pellagra and to express in a tentative fashion some of our opinions which are based thereon

THE FIELD WORK IN SPARTANBURG, S C.

The epidemiologic studies have led to the accumulation of a very large mass of data concerning the occurrence and distribution of pellagra in Spartanburg County, S. C., in regard to the cases themselves and their conditions in life. Some of this material has been presented in a preliminary fashion in a paper by Siler and Garrison.[1] They have summarized the matter as follows

1. Pellagra shows a striking inequality of distribution in ten townships within the county, the *township rate of prevalence* per ten thousand of population varying from 0 to 71 The city of Spartanburg, with a population of 17,517, gave a rate of 49 per ten thousand against 34 per ten thousand for the remainder of the country

2 Density of population, while showing a tendency to conform to the relative prevalence of the disease, does not alone offer an explanation of the geographic inequalities of its distribution within the county.

3 The cotton mill village population gives a rate of prevalence of 104 per ten thousand against 19 per ten thousand for the remainder of the county and against 16 per ten thousand for the rural sections alone

4 The variations in the rates of prevalence in the ten townships are in a measure proportional to the presence or absence of a large mill village population Excluding the mill village population, there is still a marked discrepancy between the townships, the rate of prevalence in the rural population ranging from 0 to 29 cases per ten thousand of population The excessive prevalence among the farming classes is found in the townships which have a relatively large mill village population

5 The white population of the county gives a prevalence of 45 cases per ten thousand, the negro population a prevalence of 9.5 per ten thousand Excluding the mill village population which is practically all white, the remaining white population still gives a rate of prevalence (25.2 per ten thousand) over two and one half times that among the negroes

6 The rate of prevalence per ten thousand for males in the county is 17, for females, 50.5 White males give a rate of 22.95 per ten thousand, white females, 87.5 per ten thousand, negro males, 3.9 per ten thousand; negro females, 14.9 per ten thousand

7 The rate of prevalence among children under 10 years of age and among adults aged 45 years and older, is practically equal in the two sexes

8 The rate of prevalence drops among males between the ages of 19 and 45 years whereas for females there is a remarkable excess of prevalence between these ages.

9 In both males and females there is a striking fall in prevalence between the ages of 10 and 20 years

10 The most significant fact with regard to occupation is the excessive prevalence of pellagra among women employed in housework.

11 The excessive prevalence of pellagra in the mill-village *population is found largely among women and children at* home during the day Among actual mill workers the rate of prevalence in the two sexes appears to be about equal

12 One half of the cases occurred singly in one family, about one fourth occurred two in one family, the remaining fourth occurred in groups of three, four or five in one family The question of the possible relative importance of family relationship and household association is still under investigation

13 Among cases occurring singly in families, the proportion of children of both sexes under 10 years of age is low and that of adult females excessively high Among cases occurring two or more in one family the proportion of young children is relatively *high, especially among males*

14 While apparently authentic sporadic cases of pellagra within the county can be traced back to as early as 1894, the disease does not appear to have occurred in any great number of cases in any year until 1908 Since 1908 the incidence rate appears to have rapidly increased each year to 1911 The number of new cases developing in 1911 appears to have been slightly greater than in 1912.

15 There was no evidence pointing to any spring and fall recrudescence of the disease in the population, so frequently referred to in the literature of pellagra There is no particularly marked tendency for the seasonal recurrence to appear in an individual during the same month, year after year

16 *Influence of Climate* Climatic conditions appear to influence the development of symptoms of the disease If during the spring months precipitation is high, temperature low and number of rainy days excessive, the appearance of acute symptoms more particularly those involving the skin, is delayed

17 *Symptomatology* It would appear that three or four years ago a large proportion of the cases observed in the county presented intestinal and nervous symptoms of great severity In 1912, in many instances, symptoms were quite mild and sometimes were confined almost exclusively to the cutaneous system, the disease appearing to be of a less virulent type in 1912 than in previous years

18 *Economic Status* In the *majority of cases* (85 per cent) economic conditions are poor and the disease is most prevalent among people of insufficient means

19 *Predisposing Diseases* General health conditions in childhood do not appear to warrant consideration as etiologic factors when the disease develops in adult life In a number of cases the development of pellagrous symptoms in children was preceded by one of the acute exanthematous diseases of childhood About one fourth of the cases gave a history of a preceding chronic disease in adult life In more than one half of the cases (62 per cent) the history was that of good health Among adult females, those most affected were married women (86 per cent) and 86 per cent of the married women had borne children A history of illness immediately preceding the development of pellagra was elicited in 59 per cent of the cases

[1] Siler and Garrison An Intensive Study of the Epidemiology of Pellagra, Report of Progress, Am Jour Med Sc, July, 1913, p 42, and August, 1913, p 238

20. Hygiene and Sanitation of Houses and Premises: The most insanitary condition found in the county is the absence of properly constructed privies. Outside of a part of the city of Spartanburg, which is supplied by a water-carriage sewage system, there is no effective provision in the county for the proper disposal of human excreta. A second striking insanitary condition is the almost complete absence of effective screening of dwellings. These two conditions present a situation highly favorable to the transmission of disease organisms eliminated in the excreta, both by direct contamination of food and person and by insects. This situation is naturally aggravated in the mill-villages and small towns by the greater congestion of houses. The absence of effective screening for dwellings gives rise to conditions conducive to the possible transfer of diseases transmitted by biting insects.

21. Dietary: Observations on the habitual use of the more common foodstuffs failed to discover any points of difference between pellagrins and non-pellagrins in the county or any facts which would seem to explain the strikingly greater prevalence of pellagra among certain classes of the population.

The most striking defect in the general dietary of the working classes, appears to be the limited use of fresh meats, the animal protein being supplied largely in the form of cured meats, of which salt pork (especially bacon) is the most important.

Unhygienic preparation of food appears to be a probable important factor in the general health of the population.

Investigation of the kind, quantity and quality of corn and corn products used in the county, failed to bring to light any epidemiologic evidence pointing to the agency of corn as an etiologic factor in the disease. The presence of two cases in our series giving a definite history of no corn consumption within two years prior to the onset of symptoms, together with several other cases in which corn products were eaten, if at all, only in small quantity and at extremely rare intervals, would seem to argue strongly against any hypothesis that corn products alone are the causative agent of the disease.

In intimate collaboration with the field party of the commission, Mr. A. H. Jennings and Mr. W. V. King, members of the staff of the Bureau of Entomology, U. S. Department of Agriculture, have pursued thorough studies of the insects which seemed worthy of attention as possible carriers of pellagra in Spartanburg County. The results obtained by these investigators have been presented in two papers.[2]

The following is quoted from their conclusions:

> Ticks, lice, bed-bugs, cockroaches, horse-flies, fleas, mosquitoes, buffalo gnats *(Simulium)*, house-flies and stable-flies *(Stomoxys)* were under consideration. Of these, horse-flies have nothing and cockroaches little to support them.
>
> Ticks and fleas are excluded on account of their scarcity and the nature of their biting habits. In view of these characteristics, it is doubtful if even the existence of an animal reservoir of infection would bring the groups into prominence.
>
> Lice and bedbugs do not account for the sex or age incidence or the rural nature of the disease; the scarcity of the former species is an additional reason for its exclusion.
>
> The rarity of mosquitoes here and the lack of coincidence between their distribution and that of pellagra for the state in general, together with the night-biting habits of the local species, which fail to account for the sex incidence, seem sufficient cause for their elimination.
>
> House-flies *(Musca domestica)* should be active if the malady is an intestinal infection in which the germ is passed with the feces, with contaminated food acting as the vehicle of infection.
>
> The buffalo gnats *(Simulium)* should be eliminated, principally on account of their biting habits and lack of intimate association with man, also possibly by their comparatively moderate abundance (in our territory). We find that in Spartanburg County they are hardly known as a pest of man and when they do attack him, the nuisance is local and largely confined to field workers. Had Sambon's theory not been advanced, these flies could hardly have attracted suspicion of any connection with pellagra in this country.
>
> The stable-fly *(Stomoxys calcitrans)* displays certain salient characteristics which seem to qualify it for the rôle of a transmitter of pellagra.
>
> The range of this one species covers and exceeds that of pellagra; its seasonal activity, likewise, is coincident with that of the disease and, although its period of greatest abundance is somewhat later than the maximum intensity of pellagra, its appearance in spring precedes that of most of the spring recurrences and new cases, at which time it is already abundant; it is an abundant species, its abundance being most manifest in rural districts, thus corresponding with the rural nature of pellagra, its numbers amply fulfilling our conception of those necessary to effective disease transmission; it bites by day only, thereby offering an explanation of the phenomenon of sex incidence and the related one of age distribution; it is intimately associated with man and habitually infests his vicinity and enters his dwellings; it bites man frequently and persistently; its longevity seems sufficient for the development of a hypothetic causative organism; it is readily and frequently carried long distances and might thus account for the occurrence of sporadic cases of the disease.

THE LABORATORY WORK IN NEW YORK

The material for the studies made in New York was obtained by sending patients suffering from pellagra from the field headquarters in South Carolina to the Post-Graduate Hospital in New York City. Altogether fifteen patients were sent to New York during the summer. All these patients showed a typical eruption on the skin and there was considerable variation among them as to the severity of the disease, stage of eruption, general physical vigor and financial status. The detailed observations on these patients have not yet been published. One of them remained under observation in the hospital only two days and was then removed to the house of relatives near New York. The other fourteen patients remained under observation until the acute manifestations of pellagra had disappeared and the physical condition of the patients warranted their return home. No specific medication was employed during the attack of pellagra in any of the cases but arsenic was given to two of the patients, after the acute manifestations of the disease had passed, in the form of sodium cacodylate in one case and as Fowler's solution in the other. The detailed observations on these cases and their subsequent history we hope to present in a later report.

The material for laboratory examination was largely obtained from these patients, but in addition samples of blood-serum, blood-films and some other material were obtained from patients in South Carolina and sent to the laboratory in New York.

The histology of the blood was studied by Dr. O. S. Hillman, Lecturer in Pathology at the New York Post-Graduate Medical School, and his report has already appeared.[3] He found a variable degree of chloranemia—not constituting, however, a prominent feature of the disease—and not infrequently a leukocytosis, apparently inexplicable in the light of our present knowledge of the disease. Lymphocytosis was present in the great majority of cases and may be correlated with the general cachexia of the patients and with the presence of digestive disorders. No characteristic or constant variations were detected in the large mononuclear leukocytes or in the eosinophil cells.

[3] Hillman: Some Hematologic Findings in Pellagra, Am. Jour. Med. Sc., April, 1913, p. 507

The chemical studies on the patients in New York were carried out by Prof. V. C. Myers and Dr. M. S. Fine and have been reported in detail.[4] The study includes analyses of the gastric juice, quantitative estimation of the food intake and quantitative analysis of the urine and feces of the patients during certain periods of their stay in the hospital. The results of this work have been summarized as follows:

> The ability of individuals suffering from pellagra to utilize the various foodstuffs as indicated by our series of fifteen experiments appears to be only slightly if at all below the normal.
>
> The elimination of mineral and nitrogenous constituents in the urine is such as would be anticipated under the dietary and physical conditions of the individuals. A lowered physiologic efficiency is indicated by the low creatinin coefficients and the elimination of small amounts of creatin in the urine. The presence of a few hyaline casts in about 45 per cent. of the cases points to some possible irritation of the kidney.
>
> Anacidity is a condition common in pellagra, found in eight of our fourteen cases. It is generally associated with an entire absence of pepsin, or with pepsin in only very minute quantities.
>
> Individuals suffering from pellagra show a marked indicanuria, which is excessive in the cases with gastric inefficiency. Though the ethereal sulphate hardly parallels the indoxyl-potassium sulphate, the quantities eliminated are much higher where anacidity exists and they furthermore hold a higher ratio to the inorganic sulphates.
>
> The feces contain decidedly abnormal amounts of indol and skatol, especially the latter.
>
> The presence of excessive amounts of indican in the urine, associated with a high elimination of ethereal sulphates, when considered in connection with the abnormal amounts of indol and skatol in the feces, points to some unusual bacterial conditions in the intestine. From the data at hand this putrefaction would appear to take place rather high up in the intestine.

The bacteriologic studies[5] were directed more particularly to the possible relation of intestinal bacteria to pellagra and a large number of agglutination tests were made with various bacterial strains. One of these seemed to react with the blood of pellagrins more frequently than with blood of other individuals, but we have not succeeded in establishing a specific relation of this organism to the disease. The quantitative changes in the bacterial flora of the feces are such as might be expected in irritation of the digestive tract. Numerous attempts to produce the disease in monkeys (*Macacus rhesus*) by the injection of defibrinated blood were without definite result.

RELATION OF THE REPORTED OBSERVATIONS TO THE VARIOUS THEORIES CONCERNING THE ETIOLOGY OF PELLAGRA

The theory that pellagra is due to the ingestion of maize or maize products, either good or spoiled, seems to us wholly inadequate to explain the distribution of the disease actually observed in Spartanburg County, S. C., in 1912, not only because typical severe cases of the disease were observed in those who had abstained from the ingestion of corn for a considerable time, but also because there could be discovered no essential difference in respect to the consumption of corn between those suffering from pellagra and those free from the disease.

The conception that pellagra is an infectious disease in some way transmissible from person to person seems to us to be strongly supported by many of the field observations. The higher incidence of pellagra in the more populous districts and the indications of its occurrence in definite foci are in accord with this idea, and, furthermore, the definite tendency to self-limitation of the attack in the absence of specific therapy and during the continuance of a corn diet bears a very suggestive resemblance to the course of an infectious disease. All the members of the commission and every one of the investigators associated with us in the work have come to regard pellagra as an infection in all probability and many of us would state that as our opinion without any reservation whatever.

Concerning the particular mode of transmission of the disease, the observed evidence does not appear to us to be at all conclusive. The theory of Sambon that pellagra is transmitted by a blood-sucking fly of the genus *Simulium* is based on epidemiologic evidence and apparently to a large degree on the conception that pellagra is a disease of field workers and those who go frequently into the fields. In Spartanburg County pellagra appears to be more especially prevalent in the factory villages and has a higher incidence in the City of Spartanburg itself (population 17,517) than in the less thickly populated remainder of the county. Furthermore, the adult males (the class of the population from which the field workers are largely drawn) show a striking relative freedom from the disease in our statistics. Indeed, one may go farther and say that pellagra in Spartanburg County, although it shows a tendency to attack all classes of the population, is more especially a disease of the women and children in the villages of the cotton-mills. Furthermore, it may be stated that in spite of the abundance and universal occurrence of *Simulium* in the area studied, we have been unable to elicit a history of frequent biting of man by buffalo gnats or black flies in Spartanburg County and this point has been inquired into with special care in the cases of pellagra observed. The experience of the field workers of the commission itself, who have spent day after day in the homes and environs of the pellagrins in Spartanburg County, has failed to note a single instance in which anyone of them personally has been attacked by a fly of the genus *Simulium* during the season of 1912.[6]

A comprehensive consideration of the insect life in the county undertaken by Mr. A. H. Jennings and Mr. W. V. King of the Bureau of Entomology, U. S. Department of Agriculture, has led them to the conclusion that if the distribution of pellagra is to be accounted for by a blood-sucking insect, the observed facts in Spartanburg County point to *Stomoxys calcitrans* as the most probable insect carrier. This opinion is shared by the members of the commission. We do not regard the evidence of transmission of pellagra by a blood-sucking insect in this county as at all conclusive, but we do consider it an important field for further observation.

The possible relation of an insufficient diet to the occurrence of pellagra has received careful consideration and we are inclined to ascribe considerable importance to it, not as the sole or essential cause of pellagra, but as a predisposing factor. The foods rich in animal protein, namely, meat, milk and eggs, although apparently used in abundance by a few individual pellagrins in our series, are, nevertheless, conspicuous by their deficiency in many of the cases. The use of these foods may perhaps be

[6] During 1913 two instances of biting by gnats of the genus *Simulium* have been noted by the investigators.

20. Hygiene and Sanitation of Houses and Premises: The nost insanitary condition found in the county is the absence f properly constructed privies. Outside of a part of the city f Spartanburg, which is supplied by a water-carriage sewage ystem, there is no effective provision in the county for the roper disposal of human excreta. A second striking insaniary condition is the almost complete absence of effective creening of dwellings. These two conditions present a situaion highly favorable to the transmission of disease organisms liminated in the excreta, both by direct contamination of ood and person and by insects. This situation is naturally ggravated in the mill-villages and small towns by the greater ongestion of houses. The absence of effective screening for wellings gives rise to conditions conducive to the possible ransfer of diseases transmitted by biting insects.

21. Dietary: Observations on the habitual use of the more ommon foodstuffs failed to discover any points of difference etween pellagrins and non-pellagrins in the county or any acts which would seem to explain the strikingly greater revalence of pellagra among certain classes of the population.

The most striking defect in the general dietary of the orking classes, appears to be the limited use of fresh meats, he animal protein being supplied largely in the form of ured meats, of which salt pork (*especially bacon*) is the most nportant.

Unhygienic preparation of food appears to be a probable nportant factor in the general health of the population.

Investigation of the kind, quantity and quality of corn nd corn products used in the county, failed to bring to light ny epidemiologic evidence pointing to the agency of corn as n etiologic factor in the disease. The presence of two cases n our series giving a definite history of no corn consumption ithin two years prior to the onset of symptoms, together ith several other cases in which corn products were eaten, at all, only in small quantity and at extremely rare interals, would seem to argue strongly against any hypothesis hat corn products alone are the causative agent of the isease.

In intimate collaboration with the field party of the ommission, Mr. A. H. Jennings and Mr. W. V. King, nembers of the staff of the Bureau of Entomology, U. S. Department of Agriculture, have pursued thorough tudies of the insects which seemed worthy of attention s possible carriers of pellagra in Spartanburg County. The results obtained by these investigators have been resented in two papers.[2]

The following is quoted from their conclusions:

> Ticks, lice, bed-bugs, cockroaches, horse-flies, fleas, mosquioes, buffalo gnats *(Simulium)*, house-flies and stable-flies *Stomoxys)* were under consideration. Of these, horse-flies ave nothing and cockroaches little to support them.
>
> Ticks and fleas are excluded on account of their scarcity nd the nature of their biting habits. In view of these charcteristics, it is doubtful if even the existence of an animal eservoir of infection would bring the groups into prominence.
>
> Lice and bedbugs do not account for the sex or age incilence or the rural nature of the disease; the scarcity of the ormer species is an additional reason for its exclusion.
>
> The rarity of mosquitoes here and the lack of coincidence etween their distribution and that of pellagra for the state n general, together with the night-biting habits of the local pecies, which fail to account for the sex incidence, seem ufficient cause for their elimination.
>
> House-flies *(Musca domestica)* should be active if the malady is an intestinal infection in which the germ is passed with the feces, with contaminated food acting as the vehicle of infection.
>
> The buffalo gnats *(Simulium)* should be eliminated, principally on account of their biting habits and lack of intimate association with man, also possibly by their comparatively moderate abundance (in our territory). We find that in Spartanburg County they are hardly known as a pest of man and when they do attack him, the nuisance is local and largely confined to field workers. Had Sambon's theory not been advanced, these flies could hardly have attracted suspicion of any connection with pellagra in this country.
>
> The stable-fly *(Stomoxys calcitrans)* displays certain salient characteristics which seem to qualify it for the rôle of a transmitter of pellagra.
>
> The range of this one species covers and exceeds that of pellagra; its seasonal activity, likewise, is *coincident with* that of the disease and, although its period of greatest abundance is somewhat later than the maximum intensity of pellagra, its appearance in spring precedes that of most of the spring recurrences and new cases, at which time it is already abundant; it is an abundant species, its abundance being most manifest in rural districts, thus corresponding with the rural nature of *pellagra*, its *numbers amply fulfilling* our conception of those necessary to effective disease transmission; it bites by day only, thereby offering an explanation of the phenomenon of sex incidence and the related one of age distribution; it is intimately associated with man and habitually infests his vicinity and enters his dwellings; it bites man frequently and persistently; its longevity seems sufficient for the development of a hypothetic causative organism; it is readily and frequently carried long distances and might thus account for the occurrence of sporadic cases of the disease.

THE LABORATORY WORK IN NEW YORK

The material for the studies made in New York was obtained by sending patients suffering from pellagra from the field headquarters in South Carolina to the Post-Graduate Hospital in New York City. Altogether fifteen patients were sent to New York during the summer. All these patients showed a typical eruption on the skin and there was considerable variation among them as to the severity of the disease, stage of eruption, general physical vigor and financial status. Numerous attempts to produce the disease in monkeys (*Macacus rhesus*) by the injection of defibrinated blood were without definite result.

RELATION OF THE REPORTED OBSERVATIONS TO THE VARIOUS THEORIES CONCERNING THE ETIOLOGY OF PELLAGRA

The theory that pellagra is due to the ingestion of maize or maize products, either good or spoiled, seems to us wholly inadequate to explain the distribution of the disease actually observed in Spartanburg County, S. C., in 1912, not only because typical severe cases of the disease were observed in those who had abstained from the ingestion of corn for a considerable time, but also because there could be discovered no essential difference in respect to the consumption of corn between those suffering from pellagra and those free from the disease.

The conception that pellagra is an infectious disease in some way transmissible from person to person seems to us to be strongly supported by many of the field observations. The higher incidence of pellagra in the more populous districts and the indications of its occurrence in definite foci are in accord with this idea, and, furthermore, the definite tendency to self-limitation of the attack in the absence of specific therapy and during the continuance of a corn diet bears a very suggestive resemblance to the course of an infectious disease. All the members of the commission and every one of the investigators associated with us in the work have come to regard pellagra as an infection in all probability and many of us would state that as our opinion without any reservation whatever.

Concerning the particular mode of transmission of the disease, the observed evidence does not appear to us to be at all conclusive. The theory of Sambon that pellagra is transmitted by a blood-sucking fly of the genus *Simulium* is based on epidemiologic evidence and apparently to a large degree on the conception that pellagra is a disease of field workers and those who go frequently into the fields. In Spartanburg County pellagra appears to be more especially prevalent in the factory villages and has a higher incidence in the City of Spartanburg itself (population 17,517) than in the less thickly populated remainder of the county. Furthermore, the adult males (the class of the population from which the field workers are largely drawn) show a striking relative freedom from the disease in our statistics. Indeed, one may go farther and say that pellagra in Spartanburg County, although it shows a tendency to attack all classes of the population, is more especially a disease of the women and children in the villages of the cotton-mills. Furthermore, it may be stated that in spite of the abundance and universal occurrence of *Simulium* in the area studied, we have been unable to elicit a history of frequent biting of man by buffalo gnats or black flies in Spartanburg County and this point has been inquired into with special care in the cases of pellagra observed. The experience of the field workers of the commission itself, who have spent day after day in the homes and environs of the pellagrins in Spartanburg County, has failed to note a single instance in which anyone of them personally has been attacked by a fly of the genus *Simulium* during the season of 1912.[6]

A comprehensive consideration of the insect life in the county undertaken by Mr. A. H. Jennings and Mr. W. V. King of the Bureau of Entomology, U. S. Department of Agriculture, has led them to the conclusion that if the distribution of pellagra is to be accounted for by a blood-sucking insect, the observed facts in Spartanburg County point to *Stomoxys calcitrans* as the most probable insect carrier. This opinion is shared by the members of the commission. We do not regard the evidence of transmission of pellagra by a blood-sucking insect in this county as at all conclusive, but we do consider it an important field for further observation.

The possible relation of an insufficient diet to the occurrence of pellagra has received careful consideration and we are inclined to ascribe considerable importance to it, not as the sole or essential cause of pellagra, but as a predisposing factor. The foods rich in animal protein, namely, meat, milk and eggs, although apparently used in abundance by a few individual pellagrins in our series, are, nevertheless, conspicuous by their deficiency in many of the cases. The use of these foods may perhaps be regarded as an index of economic condition and the variation in the incidence of pellagra be explained as due to economic factors in general. We are inclined, however, to regard the relation of nutrition to pellagra as a more direct one. The thesis that deficiency in the quality and quantity of food can be regarded as the essential cause of pellagra seems to us not to be supported by our studies. The fact is that a poorly nourished community generally shows a higher incidence of pellagra than one on a higher plane of nutrition, and, further, that those individuals in a community who are more poorly nourished seem more liable to develop pellagra. There is abundant evidence that other weakening factors, such as exanthematous disease, childbirth and tuberculosis, may play important rôles as predisposing factors. We are inclined to lay stress on the indication apparent in our statistics that poor nutrition or other predisposing cause results in pellagra only when the individual in question has lived in a relatively close association with a previous case of pellagra. The great mass of the population living under the same general conditions of environment and using the same food but living at a greater distance from cases of pellagra escapes the disease.

[5] MacNeal: Observations on the Intestinal Bacteria in Pellagra, Am. Jour. Med. Sc., June, 1913, p. 801.

[6] During 1913 two instances of biting by gnats of the genus *Simulium* have been noted by the investigators.

Our ideas concerning the location of a hypothetic infectious agent in the body of the pellagrin and the exact mode or means by which it gains the body of a new victim are very indefinite. The possibility of transmission by blood-sucking insects has already been considered. This hypothesis calls for the presence of the parasite in the blood or in the superficial tissues of the body. We are not aware of other important reasons for supposing that the hypothetic parasite exists in either of these situations. The gross and microscopic appearances and the distribution of the skin lesions as well as the histologic changes in the nervous system have been generally regarded by pathologists as reactions to a general intoxication rather than to local infections.[7] No micro-organisms have been recognized in these lesions. The possibility that such may exist there cannot, however, be excluded.

The possible localization of the hypothetic parasite in the digestive tract has seemed to us to be worthy of careful consideration. The observed distribution of the disease in Spartanburg County is in accord with the conception that pellagra may be transmitted through contamination of food with the excretions of pellagrins. Its greatest prevalence is in those places without adequate provision for the disposal of human wastes. The agreement between the distribution of the open surface privy close to the unscreened dwellings and the distribution of pellagra is in many instances rather striking. The quite constant presence at necropsy of pathologic lesions in the intestine, acute or chronic inflammation, ulceration and atrophy of the intestinal walls in the later stages, as well as the common occurrence of gastro-intestinal symptoms early in the course of the disease are in accord with this hypothesis, although of course they may also be explained as secondary phenomena. In our opinion the view that pellagra is an intestinal infection, transmitted by contaminated food, to which the individual is rendered more susceptible by malnutrition, poorly selected or poorly prepared food and by the common gastro-intestinal disturbances resulting from errors in diet, is a conception worthy of much further study.

These views are expressed at this time to serve as a general summary and conclusion to the series of papers which constitute the first progress report of this commission. Many, but not all of the observed facts on which it is based have been presented in detail in these separate papers. We hope to supplement and extend the observations during the second year of the investigation and expect to present in a later report results of all the work in greater detail, together with ample discussion.

SUMMARY

1. The supposition that the ingestion of good or spoiled maize is the essential cause of pellagra is not supported by our study.

2. Pellagra is in all probability a specific infectious disease communicable from person to person by means at present unknown.

3. We have discovered no evidence incriminating flies of the genus *Simulium* in the causation of pellagra, except their universal distribution throughout the area studied. If it is distributed by a blood-sucking insect, *Stomoxys calcitrans* would appear to be the most probable carrier.

4. We are inclined to regard intimate association in the household and the contamination of food with the excretions of pellagrins as possible modes of distribution of the disease.

5. No specific cause of pellagra has been recognized.

CLOSED TUBERCULOUS PYONEPHROSIS

H. A. FOWLER, M.D.
WASHINGTON, D. C.

Closed pyonephrosis is one of the most unusual and uncommon complications of renal tuberculosis. As a result of the extensive pathologic changes associated with this form of kidney infection the renal pelvis or the ureters may become completely occluded so that the secretion from the kidney no longer reaches the bladder. This process is called "autonephrectomy" and the resulting condition "closed tuberculous pyonephrosis," or "pyonephrosis tuberculosa occlusa."

This condition is of great surgical interest on account of its rarity as well as the great difficulty experienced in the majority of cases in making a positive diagnosis before operation. Smirnow was able to collect reports of only twenty-four cases scattered through the literature. These he briefly abstracts in a recent paper and adds a personal observation. In this series of cases it is noteworthy that not a single one was reported from this country, and only one case (Whipple) is reported in the English literature. While this complication is comparatively rare, it hardly seems possible that it is as rare as these statistics would indicate. It is significant, however, that Kapsammer records only three in his large series of operations for renal tuberculosis, while not a single one is reported by Israel. Moreover not more than three cases have been reported by any one observer. That the diagnosis is often difficult, or even impossible in some instances before operation, is evident from the fact that in the series collected by Smirnow the condition was recognized and accurately interpreted before operation in only a few cases (six or seven). Without the data furnished by the cystoscope and ureter catheter one had to depend on the older clinical methods of examination for the diagnosis. It was impossible by these means to determine accurately, in certain cases, which was the healthy and which the diseased organ. When the diseased kidney was insensitive and not palpable, while the healthy one was sensitive, palpable and enlarged, the latter has been mistaken for the diseased kidney. The mistake has been made of removing the only functioning organ.

It is probably safe to say that no other condition of the kidney presents greater difficulties in the way of an accurate diagnosis than closed tuberculous pyonephrosis in certain cases. Even with the aid of the newer methods of examination these difficulties are at times insurmountable and a definite preoperative diagnosis is impossible (Zuckerkandl's first case). Closed tuberculous pyonephrosis results from the occlusion of the pelvis of the kidney or the ureter at some point. This may occur in the kidney or ureter, usually at the lower end of the ureter. The resulting anatomicopathologic condition will depend on the number and the location of the strictures as well as on the time when the permanent occlusion takes place. If the stricture occurs at the lower end of the ureter, the latter is generally dilated, together with the renal pelvis; if at the upper end, the ureter will be permeable up to the point of the occlusion, but not dilated, and the renal pelvis and calices may be enormously distended. When the occlusion takes place relatively early, there is generally dilatation above the stricture; if, on the other hand, this occurs gradually and relatively late the kidney may become completely destroyed, and only remnants of the organ will be found at operation, surrounded by dense fibrous tissue.

We find, therefore, that cases of pyonephrosis tuberculosa occlusa fall naturally into two main groups, depending on the presence or absence of renal distention: (1) those presenting a lumbar or abdominal tumor and (2) those in which there is no tumor present and the affected organ is atrophic.

The majority of cases belong to the first group. These patients usually seek relief on account of the swelling in the lumbar region or the upper abdomen, associated with marked pain.

The size of the tumor will depend on the distention of the kidney and its pelvis, and naturally varies widely in different cases. Exceptionally it may attain enormous proportions; in one case (Delbet) the pyonephrotic sac contained 4 liters (about 4 quarts), in another (Tuffier) 2 liters, and in a third (Krausse) 1 liter. Very confusing from the standpoint of diagnosis are the cases in which the abscess ruptures and the pus burrows down along the psoas muscle and points at a lower level. In such cases the condition may be mistaken for one of spinal disease (Simmons' first case).

To the second group belong the cases with extensive renal destruction without distention. The kidney is gradually destroyed by cavity formation and advancing sclerotic changes with fibrous and fatty transformations. In this way the pelvis may be completely obliterated and replaced by a dense deposit of fatty tissue. The small cavities within the kidney substance are surrounded by dense fibrous tissue which completely replaces the renal parenchyma.

The affected kidney is atrophic and at operation is found buried in a dense fibrous tissue. Zuckerkandl was the first to call attention to these cases in his paper before the German Urologic Society in 1907, in which he reported three cases. The difficulties in the way of a correct preoperative diagnosis are well illustrated in the first case. The bladder was so extensively involved with tuberculous ulcers that it was impossible to obtain separate urines. One kidney was large, palpable and tender, while the other was insensitive and not palpable. It was natural to assume that the large kidney was the diseased one. It was only by exposing both kidneys that the real condition was revealed, that the enlarged kidney was the healthy one and had undergone compensatory hypertrophy, while the other was sclerotic and pyonephrotic.

In pyonephrosis tuberculosa occlusa the pathologic changes are not limited to the kidney and ureters, but the infection may extend to the surrounding tissue. This extension occurs directly by the rupture of the pyonephrotic sac or indirectly by the lymph channels. In such cases the perirenal and periureteral tissues are thickened by deposits of dense fibrous and fatty tissue which obscure the anatomic landmarks and make operative interference extremely difficult and tedious. The bladder, too, often becomes secondarily involved by direct extension and complicates the clinical picture.

As suggested by Smirnow the cases of pyonephrosis tuberculosa occlusa may be divided into three clinical groups from the standpoint of diagnosis:

1. The bladder is tuberculous. In the region of the supposedly diseased kidney a large tumor, the pyonephrotic sac, is found. The ureter on this side is impermeable. Diagnosis is easy.

2. The bladder is normal. One ureter is impermeable and on this side there is a tumor in the kidney region. Diagnosis is possible from the history of the case, and symptoms referable to other organs.

3. The tuberculous involvement of the bladder is far advanced and cystoscopy is impossible. An enlarged kidney can be palpated. Diagnosis is only possible by exploratory incision. The enlarged kidney may be healthy and only hypertrophied, while the other kidney is atrophic and tuberculous.

REPORT OF CASE

In February I was called in consultation by Dr. Selhausen to see a young man who he thought had trouble with his left kidney. He gave a history of bladder trouble dating back twelve years. This began with marked and painful urination. The urine contained pus and blood at times. He was examined by Dr. George Walker of Baltimore, who found that his bladder was ulcerated and that the urine contained tubercle bacilli. He was given the usual treatment for tuberculosis of the bladder employed at that time and was advised to go to New Mexico to live. During the next five or six years he lived in Las Vegas, N. Mex. During that time his general condition did not improve and he returned to Washington looking and feeling badly, and with the same urinary symptoms. Urination was so frequent that he had to wear a rubber urinal.

Two years ago he consulted Dr. Young of Baltimore. At that time his bladder capacity was only 30 c.c. Dr. Young was unable to catheterize his ureters, but suspected a left pyonephrosis and advised him to have an operation, but this was refused.

His condition remained about the same until about three weeks before I saw him, when he developed a fever and complained of pain in the left kidney region, extending up under the ribs. Because of the fever, pain and increasing weakness he had been confined to the house for the past three weeks. At the time of our first visit the patient was confined to his bed and complained of pain in his left side, which was sore and tender. He looked and felt ill, his complexion was sallow and he was thin and cadaverous. Examination showed a distinct bulging in the left loin, most prominent just below the costal border in the posterior axillary line. The overlying skin was reddened. This was tender to slight pressure and distinct fluctuation could be made out. The right kidney could not be felt. A hard, small nodule could be felt in each epididymis, which he stated had been present for several years. The urine was perfectly clear, free from shreds and amber in color. The temperature was 101 F.

The diagnosis of perirenal abscess was made and the patient was sent to the university hospital. The same evening an aspirating needle was introduced and a large quantity of thick pus was evacuated. The following day, under cocain, this abscess was opened and a large cavity was found extending upward superficially underneath the ribs toward the pleural cavity. This was evacuated and drained by two rubber tubes.

He improved rapidly after this operation. The fever subsided and he gained 20 pounds in weight during the next three months. Meanwhile the wound continued to discharge profusely despite daily irrigations. The cavity contracted down to a sinus occupied by the drainage-tube, extending about 5 inches upward beneath the ribs. The discharge continued very profuse.

In June, 1911, four months after the operation, it was evident that the patient was losing ground. He again developed a rise in temperature, became weaker and began losing weight. A cystoscopic examination was made at this time and revealed an interesting condition. The bladder was definitely contracted, holding about 90 c.c. The bladder wall was in general normal. The trigon appeared to be pulled around to the left about 45 degrees, so that the right ureteral opening was directly in the midline, while the left opening was drawn far up on the left side. The left opening was indistinct and was surrounded by a hemorrhagic area of inflammation. The right opening was large, patulous and emitted urine at frequent intervals. There were no ulcers present and no tubercles could be seen. Nothing could be seen to escape from the left ureter. A catheter was introduced into the left ureter and passed without difficulty to the pelvis of the kidney. Nothing was obtained through this catheter. Indigocarmin was injected; this appeared from the right ureter in nine minutes. A colored solution was injected into the left ureter in considerable quantity to demonstrate if possible a connection between the pelvis of the left kidney and the sinus of the previous operation. No color appeared and the dressings were not subsequently soiled. It was evident from this examination that the left kidney was not functioning, and there was no demonstrable connection between the kidney pelvis and the sinus from the previous operation. There was no stricture of the left ureter. It was also evident from the patient's general condition that there was a deep focus of infection which had not been reached and which was responsible for his fever and other signs of toxemia. It was presumed that this deep abscess was in the kidney and that the condition was one of closed pyonephrosis, but its relation to the abscess opened four months before was not clear. An exploratory operation on the kidney was advised and accepted.

On June 2 a lumbar incision was made. The scar tissue was pronounced, infiltrating the muscle and obscuring the anatomic landmarks. The lower pole was exposed and stripped of its thickened capsule. Over the upper pole the capsule was greatly thickened and so firm and adherent to surrounding structures that it was with difficulty separated. In the process of freeing this the finger broke through suddenly into a large abscess cavity, and pus in large quantities welled up into the wound. This cavity was rapidly enlarged, exposing an abscess cavity quite as large as one's fist. This cavity was separated from the abscess cavity, opened at the first operation, by the thickened diaphragm. It was evident that the original trouble was at the upper pole of the kidney. The abscess had made its way through the diaphragm and involved the pleural cavity in a tuberculous empyema. It was the abscess in the latter situation which had pointed below the costal margin and was opened at the first operation.

The remnants of the renal parenchyma at the lower pole were removed by merely twisting this off with a pair of clamps. There was very little bleeding. The pelvis and ureter were not identified and were not searched for on account of soiling the wound. Rubber drains were used in the separate cavities, and partial closure of lumbar incision with gauze packing about the drains.

Hemorrhage during the operation was not abundant and was easily controlled. The patient reacted well but was very weak and the pulse was very rapid. On the third day after the operation the bowels were opened with a laxative. A fecal fistula was formed and there was profuse discharge of feces through the wound. Careful examination showed that the fistula had formed at the site of the abscess in the upper pole. The patient's condition grew worse, the abdomen was tender, there was muscular rigidity, the temperature was subnormal and the pulse-rate increased. In the course of the next few days the tenderness and rigidity disappeared, but the condition continued desperate. The fecal fistula continued to discharge, while the drainage of the pus was profuse. The remaining kidney continued active. The patient gradually grew weaker and died ten days after the operation. No necropsy was permitted.

There are several interesting features in the case here reported.

The history of the case covers a period of over twelve years. The first symptoms complained of were referable to the bladder—frequency, urgency, and tenesmus. The lesion in the kidney had unquestionably existed for some time without giving rise to any localizing symptoms. It was only when the bladder became involved in a descending infection that symptoms were produced that attracted attention and forced the patient to consult a physician. At this time the examination showed a marked ulcerative cystitis. The urine contained considerable quantities of pus, and blood and tubercle bacilli were found. When I first saw him, twelve years later, the urine was perfectly clear. Cystoscopy showed a practically healthy bladder mucosa, but a reduced bladder capacity.

The absence of the marked ulcerative cystitis which was present at the first examination was due unquestionably to the blocking of the communication between the infected kidney and bladder. With the flow of infected urine from the kidney over the bladder mucosa cut off the vesical lesions cleared up and practically entirely disappeared. This is an interesting observation and shows how the bladder tuberculosis sometimes heals when the primary source of the infection has been removed by nephrectomy. Here autonephrectomy has accomplished, so far as the bladder was concerned, what surgical nephrectomy at times accomplishes in similar cases. This case illustrates very well the fact that autonephrectomy cannot be considered a curative process. The subsequent history of the patient warns us against trusting to the natural cure of renal tuberculosis by autonephrectomy.

Another interesting feature is the rupture of the abscess in the upper pole through the diaphragm, producing a tuberculous empyema. It was the pus from the pleural cavity gravitating to the lowest point and producing a fluctuating swelling at the costal border that first attracted attention to the region of the kidney. I have not met a similar complication among the cases of closed pyonephrosis reported in the literature. The position of the abscess in the upper pole directly beneath the diaphragm, and the dense fibrous tissue surrounding the whole kidney and closely adherent to the contiguous structure, probably accounts for the pus taking this course. The dense scar tissue doubtless prevented the pus from gravitating downward along the psoas muscle and ureter and outward toward the surface. At the first operation it was the abscess in the pleural cavity that was opened and drained. The primary focus in the kidney remained closed until the second operation.

A further interesting feature in the case is the fecal fistula which formed when the bowels were opened for the first time following the operation. This complication following operation for pyonephrosis and perirenal abscess has been noted, but is, fortunately, very rare. The fistula forms independent of any injury to the peritoneum or bowel. I am certain that in our case no injury was done to either the peritoneum or bowel. The discharge of bowel contents through the wound did not occur until after a laxative had been given. The most probable explanation of this complication in our case would appear to be that the peritoneum overlying the abscess in the upper pole of the kidney became involved and the loop of bowel became adherent at this point. When the support was removed by drainage of the abscess, the peritoneum and bowel gave way before pressure.

2006 Columbia Road.

GASTRIC ULCER FROM OVERWORKING THE STOMACH

R. H. PIERSON, M.D.
Captain Medical Corps, United States Army
FORT GIBBON, ALASKA

It has been my fortune during the past few months to observe seven cases of gastric ulcer which originated under conditions which are not encountered in the experience of the ordinary practitioner and which throw light on the conditions that in some instances at least bring about this trouble. The cases occurred in practice in the town of Tanana, Alaska. This town is situated in the central portion of the territory on the Yukon River. All the cases of gastric ulcer were in men who had been living under conditions peculiar to the country and to a primitive mode of life. They were all strong, robust men who had endured lives of hardship with hard work of the camp and trail. During the same period in the practice of this community there were no other cases of gastro-intestinal disease. Gastric ulcer appears to be about the only kind of digestive disturbance these men have.

Of course so small a number of cases is too few to form a basis for generalization or for conclusions as to the causes of gastric ulcer. These cases are of interest in demonstrating that some conditions will cause the stomach to ulcerate. They are also of interest in that when the conditions which had caused the development of the ulcer were corrected the symptoms promptly subsided in every case treated. No operative interference was required to effect a cure.

In all of these cases the clinical manifestations were typical. Three were of the hemorrhagic type. In two of them there were profuse and repeated hemorrhages from the stomach, of 500 c.c. or more. There is no reasonable doubt as to the correctness of the diagnoses.

All of the men were engaged in outdoor occupations. They were hunters, trappers and miners. One was a telegraph operator at an isolated station on the Yukon River. He had, however, lived under the same conditions as the other patients. His diet had been the same.

The conditions of life in Alaska are such that few but strong men remain in the country and none but strong men can follow the trail and live in the woods and camps for a long time. The diet is such as the country affords, with the addition of tea, coffee, some liquor and canned goods. The meat is mostly bacon, or canned meats, and game, the latter being plentiful; meat forms a large share of the food. Vegetables are few. The bread is either baking-powder biscuit or the "sour-dough" hot cakes. From October until June there are no fresh vegetables. In some instances berries, put up with equal amounts of sugar, uncooked, were eaten as a preventive of scurvy. There was usually an attempt to keep potatoes unfrozen, which could be eaten as an antiscorbutic. Scurvy did not appear to be a factor in the cases which were treated for gastric ulcer, though it would seem that it might reasonably be taken into consideration as a contributing cause, especially in the hemorrhagic cases. The use of alcohol was carried to excess in but one case. The other men lived under conditions which made it very hard for them to get liquors. They were not hard drinkers, even when liquor could be easily obtained.

The essential factors which all these cases had in common were the following: 1. In all instances the food was rough. 2. There was a large proportion of nitrogenous food. 3. The cooking was poor. 4. Few green vegetables were used. 5. The meats eaten were either salt or dark meats, mostly game. 6. On account of the hard life which these men lived and the conditions of extreme cold they became accustomed to eat immense quantities of food which had a high caloric value.

These men needed a great amount of food to furnish energy for the strenuous physical exertion which their method of life necessitated as well as to maintain the heat of the body while they were exposed to the rigors of and extremely cold climate. The body called for an excessive amount of nourishment and the stomach had to furnish it. To furnish heat and muscular energy for the body the stomach was given coarse food, which was mostly nitrogenous and which was in some instances poorly cooked. Taking into consideration what the stomach had to do and what it had to do it with, it appears that the stomach deserves high credit for the way it attempted to do its work. One sample meal consisted of one duck, four potatoes and six baking-powder biscuits. A pound of beans and a pint of coffee is not an unusual simple meal for one of these men.

For a time the patients got along well. After a year or two there were usually symptoms of gastric ulcer. The histories usually gave the record of pain after eating. Indigestion and pain in the stomach would come on toward spring. The men found that they needed a change of food. They were no longer able to eat beans. There are a great many men who only reach this stage of the disease. They come to town where they can get eggs and raised bread and green vegetables. Some of them take warning from the premonitory symptoms and pay more attention to their diet. These men are suffering from the early symptoms of gastric ulcer. They cure themselves by changing their diet in response to the demands of Nature, which are manifested by cravings for certain foods that will be better suited to the stomach. After all, Nature is our best physician, and if we but obey her demands many of the diseases from which we suffer will be cured in their incipiency.

The stomach is a willing and a faithful servant to most of us. When our bodies demand nourishment the stomach seldom complains. It seems to know when it is required to do its best because the body needs food or when food is simply being thrown into it for the satisfaction of an overindulged appetite. When the body needs food the stomach usually does its best to furnish nutrition. When unneeded food is placed in the stomach, the stomach resents the imposition and refuses to digest the food. Among city dwellers who overload their stomachs we get indigestion. Among frontiersmen who have to overtax their stomachs we find the stomachs doing their best to accommodate their activities to meet the demands of the system. Such stomachs get to secrete a strong and excessively acid gastric juice. They digest almost any kind of food and enormous quantities of it. After a while they get to digest their own walls. It is a wonderful demonstration of the way in which Nature will attempt to meet demands which are made even though the demands are most unreasonable. When we consider the causes and see the results it is not surprising that these men suffer from gastric ulcer and not from simple indigestion. They never acquire gastroptosis or atony. They have ulceration, which is the disease of strong stomachs that have been overworked rather than weak stomachs that have been abused.

This conception of the etiology of gastric ulcer may not apply to cases which come to the observation of practitioners who have to deal with patients most of whom follow the sedentary occupations of city dwellers. The fact that the causes which have been described have resulted in gastric ulcer is not without interest or significance. It suggests a rational line of treatment.

The most valuable article on the subject of treatment of gastric ulcer which has come to my notice has been that by Dr. J. W. Weinstein.[1] The treatment used in my cases followed the principles which are outlined by him. It is a treatment which has for its object the correction of the perverted natural process. There has been in a case of gastric ulcer a hypertrophy of the hydrochloric and peptic-secreting glands. The glands have become abnormally active. The muscular tone of the stomach is usually below normal. The stomach is apt to be dilated, but not below the normal level. It quickly regains tone. At the end of a week's treatment there was no more dilatation. It is probable that the fact that the patients treated were strong men, otherwise sound, materially aided in securing prompt recovery with medical treatment alone. When Nature is given a fair chance she will work her own cures, which is fortunate for the medical profession as well as for many of our patients. A little assistance is often all that is required by Nature for the perfection of a cure.

TREATMENT

Following is a brief outline of the treatment employed:

1. Rest in bed. This is essential for the first week; without it prompt results will not be secured.
2. The amount of gastric secretion is diminished by the use of belladonna or atropin given before meals.
3. Bismuth in some form is used before meals to protect the stomach walls.
4. When there is hyperacidity or pain over the pyloric region from 15 to 20 grains of sodium bicarbonate are given (four or five soda mints). It is well to give 15 grains of bicarbonate half an hour after each meal for the first week whether or not there is pain and distention.
5. A saline aperient is used every morning. Sodium phosphate in hot water has been found satisfactory.
6. A cold pack is applied over the stomach every night. The patient wears it through the night and takes it off in the morning. It is quite possible that the pressure by this pack over the stomach is beneficial. It seems to give some relief to the patients. They have less flatulence.
7. The food is to be eaten slowly, well chewed and is of a moderate quantity. The stomach is never loaded.
8. The foods which are allowed are those which call for a minimum of hydrochloric digestion. It is best to use foods which are largely digested in the intestine and which do not stimulate the functions of the stomach. The stomach is given a rest. Carbohydrate foods allowed are stale bread, crackers, shredded wheat biscuit, cereals with milk and little sugar, toast, corn-starch, tapioca. No nitrogenous food is permitted at first; later milk, then soft boiled or poached eggs, still later boiled fish. The fruits permitted are baked apples (pulp alone), ripe bananas (one at meal time), orange or grape juice in moderate quantities. The vegetables allowed are mashed potatoes, lettuce, asparagus tips, spinach or beet greens (tender leaves with salt and olive oil only as a seasoning). Butter and olive oil, weak tea or milk may be taken.

Foods not allowed are: stimulants of any kind; seasonings (other than salt or olive oil); meats; beef extracts; soups other than vegetable; salt or dried fish: any vegetable foods which have heavy fiber or husks; an excessive amount of sweets.

Tobacco cannot be used for the first ten days. After that time it can be used in moderation, but not chewed.

The treatment consists essentially in giving the stomach a rest and inhibiting the production of its secretion. This is accomplished by checking part of the secretion through the use of belladonna, by diminishing the activity of the secretion through the neutralizing action of its acid, by selection of foods which do not stimulate the gastric secretions and by diminishing the amount of food which is consumed. By the rest in bed the physiologic processes of the body are slowed up. The demand for food drops. A man who has been living an outdoor life with fairly active exercise in a cold climate will require from 4,500 to 6,000 calories of food to maintain the bodily heat and supply energy for his work. As soon as he is put to bed in a warm room the demand for fuel drops to from 1,600 to 2,000 caloric value. When, in addition to this relief of the stomach from the demands which have been made on it, the character of the food is changed so that it is easily digested and that most of it is digested in the intestine and not in the stomach, then in comparison with what it has been doing, the stomach is afforded an almost complete rest. This treatment is simple and rational. It has for the few cases treated proved itself to be extremely effective.

In the cases which were treated by this method there was no pain remaining at the end of the first week. When practicable the patient was required to remain in hospital for one week longer. At the end of that time the patients were ready to leave the hospital and complete the cure at home. In each case the nature of the trouble was carefully explained to the patient and he was given a typewritten letter of instructions for continuation of treatment, with diet lists of foods which were and which were not allowed. Thus far there have been no recurrences.

The results which have been obtained in the treatment of these few cases are unusual. It is not believed that such results will be obtained in treatment of persons who live in cities. We have had here exceptional material to work with. The men have all had excellent general constitutions. The results are interesting to the general practitioner as illustrating what cures can be accomplished under the most favorable circumstances and as demonstrating the soundness of the principles on which this method of the medicinal treatment for gastric ulcer is based.

The general practitioner has come to regard ulcer of the stomach as a disease which is not readily amenable to medicinal treatment. He is apt to turn his case over *to the surgeon as soon as the diagnosis has been made.*

---

[1] Weinstein, J. W.: A New Method of Treatment of Ulcer of the Stomach, THE JOURNAL A. M. A., *Sept. 28, 1912, p. 1151.*

No greater injustice could be done the patient. He has a trouble which is probably quite submissive to suitable treatment which is systematically carried out. He cannot be simply given a pill and a bottle of pepsin and cured. The fault in treatment of gastric ulcer has been largely that the physician has, until this time, given only a haphazard treatment. When the patient comes to his office the physician usually gives him some sort of a digestive ferment or a bitter tonic. He may even make a stomach analysis or wash out the stomach as frequently *as the patient has sufficient funds to pay for.* There is seldom an inquiry made as to the patient's mode of life or any attempt to correct the gross errors in his regular habit and method of life.

We are too apt to regard the stomach as a mere receptacle for food and drugs. It has been too little respected. The stomach can almost think. It knows what kind of food is put into it and tries to furnish a different kind of digestive juice for each kind. It knows when it is being imposed on or when it is simply being made to do its share of the work which the other organs of the body are doing. As a usual thing the stomach is as faithful and as uncomplaining as a beast of burden. It may be scalded with hot drinks and chilled with ices. It may be heaped with rubbish and soaked with gallons of beer. It may be pickled with alcohol and blistered with pepper *and mustard. It may be required to convert pounds of* the roughest material into nourishment for the body and may perform the seemingly impossible task for several years without complaint. In the end the efforts which it makes to meet the unreasonable demands of its master are its own undoing. The overworked stomach, though about worn out, keeps on with its efforts to produce a strong digesting secretion. It does not need medicine or much if any treatment. It needs simply to be given relief and an opportunity to recuperate, when it will again be the docile and willing servant which it has always been.

The surgical treatment of gastric ulcer has been successful in many cases. It is particularly so in the cases of chronic flat ulcer. In this type there are apt to be the most adhesions and other anomalies which need mechanical correction. In the small, deep, perforating ulcers which are frequently of the hemorrhagic type there has been less success from operative treatment. It is just this type of ulcer which is most quickly cured by readjustment of the diet and habits of the patient to natural physiologic laws. There is great hope of success in the rational treatment of gastric ulcer. It is well known that attacks of this disease come and go. It can be demonstrated that in most cases the attacks come as a result of definite causes and that spontaneous cures result when the patient responds to natural laws.

Absence of Hydrochloric Acid After Test Meal.—It is unwise to rely on a single negative result or even a series of negative results in the estimation of HCl unless the evacuation of the stomach is carried out at varying periods after a test meal. This is illustrated in the case reported by T. Gillman Moorhead (Dublin *Jour. Med. Sc.*, Oct. 1, 1913) in a woman aged 50, suffering from pain in the stomach, flatulence, vomiting and loss of weight. A test meal of the usual Ewald type removed an hour after taking showed no HCl. Several other examinations an hour after taking the meal showed the same results. In another test in which the removal of the meal was delayed until two hours after taking, HCl was found present in considerable quantities. Subsequent tests after longer intervals also showed HCl. Moorhead calls attention to the importance of this in case cancer is suspected on account of the absence of HCl in the stomach contents after a test meal.

NOTES IN THE STUDY OF POTASSIUM MERCURIC-IODID

DOUGLAS MACFARLAN, M.D.
PHILADELPHIA

To attempt to add still further to the host of antiseptics may seem a useless endeavor. The field has already been well covered and the relative values and merits so well established that the most fastidious can now be readily satisfied. Of late years it has largely been a matter of the complementary qualities, rather than the germicidal powers, that has determined the choice of antiseptics. Indeed, at times the comparative antiseptic values seem ignored in the consideration of the less important qualities. But naturally the distinctive merit of all antiseptics should be first of all in antiseptic powers.

For this alone, then, potassium mercuric-iodid has a claim for marked consideration. No other antiseptic can justly claim such great power in great dilutions and none is of so remarkably low toxicity for its strength.

PREPARATION

Potassium mercuric-iodid has been described in New and Nonofficial Remedies.[1] Red mercuric iodid is readily soluble in alcohol or water on the addition of approximately twice its weight of potassium iodid. A new salt is formed, potassium mercuric-iodid, K_2HgI_4. Thus this salt is formed from 1 grain of mercuric iodid and $2^{1}/_{5}$ grains of potassium iodid on the addition of a few cubic centimeters of water. If not enough potassium iodid has been used the resultant light-yellow solution, though apparently clear, will deposit after a few hours a yellow sediment of the crystals of potassium mercuric-iodid. To have the ideal solution, sufficient potassium iodid should be added to give a perfectly colorless liquid, and only distilled water should be used in making it.

Boullay[2] states that a concentrated solution of potassium iodid will dissolve mercuric iodid in the ratio of 3 molecules of the mercuric salt for every 2 of the potassium salt. From such a solution, however, the crystals of potassium mercuric-iodid are prone to separate out, and often the red iodid itself comes down again. For practical purposes it is better to use the clear solution, the strength of which may be recognized from the amount of red mercuric iodid used. The small amount of potassium iodid, especially when dilutions are made, is an indifferent factor. Thus the formula of a 1 per cent. solution of *mercuric iodid in potassium iodid* would be:

Mercuric iodid	1 gm.
Potassium iodid	4 gm.
Distilled water	100 c.c.

This solution will be found quite permanent and may be kept for months without change. The liquid is clear, of metallic taste and very irritating to the mucous membranes. In dilutions which it is safe to use it shows no tendency to coagulate albumins; but it is incompatible with the organic alkaloids, with which it produces insoluble precipitates. On account of this property it has been used as a qualitative and quantitative test for the alkaloids.[3]

TOXICITY

A 1 per cent. solution gives all the effects of a mild irritant; if rubbed on the hands or applied as a wet dressing it produces a moderate hyperemia, tingling and hypersensitivity. On mucous surfaces its action is most marked. Applied by a swab to the nose or throat it causes a profuse flow of secretion, thin and watery. There is marked lacrimation, salivation and rhinorrhea which lasts for an hour or two. Sneezing is at times very severe, and this with the free discharge gives a picture closely resembling an acute attack of hay-fever. On the gastro-intestinal tract there is likewise decided irritation if taken in sufficient amount. A sense of burning in the epigastrium, nausea, vomiting and profuse diarrhea are the symptoms encountered. The drug has no apparent effect on the circulation, muscular or nervous systems, or on the genito-urinary tract.

It appears that if the local irritant effect is overcome by dilution, comparatively large amounts may be taken internally without producing severe symptoms. On a number of cases in which the drug was pushed, from 5 to 7 drops of a 1 per cent. solution was the limit of toleration, while from 15 to 18 drops of the same solution could be borne if well diluted. With a prolonged trial of the drug it seems that there is no tendency to cumulative effect. No ptyalism has been observed in any of the cases in which the strongest tolerable doses were given over a period of months. Elimination appears to keep pace fully with assimilation. Vomiting and other symptoms of gastric irritation that appear when too strong a dose has been taken soon subside when the drug is stopped. Its use, apparently, can be resumed at once after the toxic symptoms are abated.

TABLE 1—RECORDS AND SUBCULTURES TAKEN AFTER TWENTY-FOUR HOURS

	Strength of Potassium Mercuric-Iodid Solution				
	1:60,000	1:70,000	1:80,000	1:90,000	1:100,000
B. typhosus— (Bouillon)	Sterile	Sterile	Sterile	Sterile	Three small colonies on plating
Staphylococci— (Bouillon)	Sterile	Sterile	Sterile	Scattered half dozen colonies on plating	Numerous colonies
B. lactis bulg.— (Milk mediums)	Sterile	Sterile	Sterile	Trace of activity	Moderate activity
Yeast-sugar sol........	Sterile	Sterile	Sterile	Very faint trace of activity	Faint trace of activity
B. acidi lactici— (Milk mediums)	Sterile	Sterile	Sterile	Trace of activity	Activity equal to the control

EFFECTS ON PHYSIOLOGIC ACTIVITIES

In 1 per cent. solution *in vitro* potassium mercuric-iodid had no appreciable effect on ptyalin, rennet, pepsin-hydrochloric or pancreatic activity. This was verified repeatedly, and in every instance the series corresponded with the control. In respect to its activity on micro-organisms, however, a much different condition was found. Marked inhibitory and germicidal effects are seen in the weakest dilutions, and it is in this field that the drug finds its greatest usefulness.

Fermentation by yeast was prevented by the presence of potassium mercuric-iodid in dilution of 1:80,000; while in dilutions of 1:100,000 there was but a faint trace of yeast activity.

With a strain of staphylococci that was quite prolific on natural mediums, an inoculation in 1:80,000 potassium mercuric-iodid agar was sterile twenty-four hours later. A few scattered colonies (only three in one instance) appeared in the presence of 1:100,000 potassium mercuric-iodid.

A strain of typhoid bacillus did not appear in an inoculation of agar and broth mediums of 1:60,000 potassium mercuric-iodid strength. It was inhibited in dilutions up to 1:80,000 (Table 1).

A series to determine the relative activity of the germicide in relation to time showed that dilutions of 1:60,000 "killed" a typhoid strain in a period as rapid as two minutes. The procedure suggested by Park[4] of the use of contaminated pieces of thread was adopted.

The action on the flora of the gastro-intestinal tract can readily be inferred, though this matter has not as yet been definitely confirmed. At times clinical evidence seems suggestive, in the rapid disappearance of some of the intestinal diarrhea on the exhibition of this remedy.

Little, then, can be said of the noxious effects on the gastro-intestinal tract when the drug is taken in mild doses. There is no inhibition of ferment activity, and whatever harm that could occur would arise from destruction of intestinal bacteria.

As an incidental to considering effects on digestion of food it has been noted that in dilution of 1:100, 1:1,000 and 1:10,000 potassium mercuric-iodid hastens the formation of curd in milk. The stronger solutions are the more effective, a 1 per cent. solution in thirty-six hours' time leaving a firm, homogeneous, smooth curd above a perfectly clear whey. *Bacillus lactis* is inhibited by the presence of the salt in the same dilutions as previously recorded for other bacteria from 1:80,000 to 1:100,000.

USES

Before consideration of its greatest value, its antiseptic powers, it may be well to notice some incidental uses for which the drug has been recommended.

In 1834 the salt was "presented to the profession as a new remedy of remarkable powers" by Dr. William Channing of New York.[5] With the enthusiasm common to the introduction of anything new the drug was "found useful in chronic bronchitis, whooping-cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhea, leukorrhea, eruptions and scrofula." No doubt this list would have been lengthened had Dr. Channing more confidence in the credulity of the profession. A man of his experience, however, no doubt honestly and fully appreciated the fact that he had come on a remedy of value. He further reports its use in some cases of phthisis, in which he found it mitigating the symptoms and prolonging life.

---

[4] Park, W. H.: Pathogenic Bacteria and Protozoa; New York, Lea and Febiger, ed. 3, p. 108.

[5] Channing, William: Am. Jour. Med. Sc., 1834, xiii, 388.

Dr. Hildreth's[6] trial of the remedy satisfied him as to its benefits in "functional dyspepsia, amenorrhea, dysmenorrhea, leukorrhea, scrofulous affections, ascites and general dropsy." These two men used the solution of the drug in doses equivalent to from $^1/_{12}$ to $^1/_{40}$ grain of the crystals.

Its value as an internal remedy in all of the conditions mentioned is doubtful. It does, however, seem to have a marked effect on all catarrhal conditions of the mucous membranes, clearing up the common cold, apparently shortening the course of croup, and modifying the acute infections of the nose, throat and bronchi. This conclusion has been reached after careful observation and repeated trial. Nearly all patients with catarrhal conditions remark that it gives them great benefit in freeing the sticky mucus. This is particularly true in acute bronchitis. In those cases of gastritis and enteritis that exhibit much mucus the same effect has been noted. It further acts by its irritation to the mucous membrane as a mild stomachic if used in a careful dose.

In spite of frequent trials I have not obtained the effects claimed for it in leukorrhea and in menstrual disorders.

Locally, a beneficial effect has often been noted in atrophic rhinitis when applied in the nares as a swab or spray. In a dilute solution the remedy acts as a remarkable germicide and stimulant, resembling formaldehyd in its effects. The results seem more effective and permanent than those obtained with the latter. The irritant qualities of the drug exercise the secreting glands that remain, the mucus becomes thinner and more free, and the ozena rapidly subsides.

In a number of cases acute frontal sinusitis the drug has been tried by local application. Here again marked relief has been noted because of the free rhinorrhea that the irritation sets up. The free outpouring of thin mucus sweeps before it the thick purulent secretions that have backed up in the blind cavities. A possible objection to its use is the slight swelling of the mucous membrane and somewhat increased stenosis of the canals resulting. Naturally there is much danger of the promiscuous use of the drug in the nose and throat.

The French for a long time have been using potassium mercuric-iodid for syphilis and skin diseases, the prescription of preference being widely known as the "one, two, three mixture": 1 gram of red iodid, 2 grams of potassium iodid and 3 ounces of diluent, either water or alcohol. On account of its solubility, it was considered the most readily assimilated mercurial preparation. Actual experiments, however, have not been made to establish accurately this supposition. In psoriasis, cryptogenic infections of the skin and in lupus the French have long been partial to potassium mercuric iodid, using it both internally and as an ointment.[8]

In this country Dr. Archibald Church has had good success from the use of sodium mercuric-iodid for intramuscular injections.[9]

But above all these incidental uses, it is as an antiseptic that its field is greatest, it being here practically universal in its possibilities, for in great dilutions its local effects and toxicity are insignificant while its germicidal qualities still remain high. The value of these virtues can readily be realized when the following facts are again referred to: 1. The drug may be taken internally in doses of 5 drops of a 1 per cent. solution without toxic effect. 2. A 1 per cent. solution has but slight irritant action. 3. A dilution of 1:80 000, or nearly one one-thousandth of 1 per cent., exhibits marked germicidal powers.

At a glance Table 2 will give a graphic idea of where this solution stands in relation to other common antiseptics.

TABLE 2.—PARK'S TABLE OF ANTISEPTIC GERMICIDAL STRENGTH*

Alum	1 22		
Aluminum acetate	1 6 000	Ferrous sulphate	1 200
Ammonium chlorid	1 9	Formaldehyd 40 per cent	1 10 000
Boric acid	1 143	Hydrogen peroxid	1 .20 000
Calcium chlorid	1 25	Mercuric chlorid	1 ·14 300
Calcium hypochlorite	1 1 000	Mercuric iodid	1 40 000
Phenol	1 333	Pure formaldehyd	1 25 000
Chloral hydrate	1 107	Silver nitrate	1 12 500
Copper sulphate	1 200		

* Park, W. H. Pathogenic Bacteria and Protozoa, ed. 3, Lea and Febiger, p. 108.

There appears no limit to the use of potassium mercuric iodid in this field. Cases of erysipelas, acne, pustular infections of the skin of all varieties, lupus and psoriasis show remarkable results under its use. The purulent discharge of so many minor surgical cases such as infected burns, old leg ulcers and ragged wounds is rapidly cleared up. Even when the affection is somewhat subcutaneous, as in felons and boils, when there is as yet no pointing or definite formation of pus, a wet dressing of 1 per cent. potassium mercuric-iodid will usually reduce the prolonged course of the case and will frequently abort it altogether.

For the sterilization of instruments the drug is excellent, except for its tendency to tarnish if left in contact too long. This can be easily overcome by the addition of a little sodium bicarbonate to the solution. McClintic suggests the addition of sodium bicarbonate to overcome this disadvantage.

It is hoped that with such definite evidence of the value of potassium mercuric-iodid, the recommendation of its clinical results and its manifest powers in laboratory experiment, this preparation will find some disciples among those who wander indefinitely hither and thither from antiseptic to antiseptic.

1805 Chestnut Street.

EXPERIMENTAL STUDIES IN POLIOMYELITIS*

PHEBE L. DUBOIS, M.D., JOSEPHINE B. NEAL, M.D.
AND
A. ZINGHER, M.D.
NEW YORK

The establishment of abortive and meningitic forms of poliomyelitis by Wickman has thrown much light on the epidemiology of the disease. In the efforts to produce the disease in monkeys by the injections of the secretions of abortive cases, there have been varying degrees of success.

Kling, Pettersson and Wernstedt[1] report six cases in which inoculations from the mouth or intestines in abortive cases resulted in lesions characterized by degeneration rather than infiltration in the brain and cord of monkeys. The inoculation of several monkeys—the

number is not stated—gave negative results. Three of the positive results were obtained by washings done ten days, one and a half months and three and a half months respectively after the onset of the symptoms.

On the other hand, Kling and Levaditi[2] were unable to obtain results in two abortive cases. They were unsuccessful, however, in a large percentage of their typical cases. In their interesting study they point out a type of case not often described, namely, a type characterized by a short prodromal stage with headache, fever and malaise succeeded by a period of apparent good health lasting several days, after which the true attack develops with manifestations of nerve involvement which may go on to death.

Monkey 2 of our experiments seemed to show this clinical picture with respect to the objective symptoms. Kling, Pettersson, Wernstedt point out that degenerative lesions not accompanied by infiltration are characteristic of an attenuated virus, this being the type of lesion they obtained from the abortive cases. The lesions in the monkeys in our experiments showed considerable infiltration as well as degenerative changes, but the virus died out quickly.

In the summer of 1912 we passed the feces from a typical case of poliomyelitis through a Berkefeld filter and injected the filtrate intraspinally into a monkey with negative results.

Jan. 10, 1913, we were called to see a case of what we diagnosed as abortive poliomyelitis.

History.—Robert A., aged 5, reported by Dr. Spivacke. There was a sudden onset January 7, with a temperature of 102 to 106 F. of short duration, which was not followed by paralysis.

Lumbar puncture January 10; 50 c.c. clear fluid withdrawn under high pressure. Cytology: cells increased, 90 per cent. mononuclears, and a number of large endothelial cells were found. Bacteriologic examination: smear negative, culture sterile. Albumin + (slightly increased). Globulin + (slightly increased). Animal inoculation: two guinea-pigs; one died January 19, and on necropsy showed pus in the pericardium and the pleura. The other was found to be negative, February 11.

Jan. 24, 1913, Mrs. A., Robert's mother, who had been taking care of him in isolation, had her nose and throat thoroughly washed out with normal saline solution. January 25 and 26, washings were passed through a Berkefeld filter. January 27, 40 c.c. were injected intraperitoneally into a monkey. The result was negative.

Jan. 24, 1913, Robert's nose and throat washed out with normal saline. He kicked and screamed and struggled so that we could not do it satisfactorily. January 25 the washings were put through the Berkefeld filter and 20 c.c. injected intraperitoneally into a monkey.

February 14: Monkey sick.
February 17: Partially paralyzed in hind legs.
February 18: Drags right foot; chloroformed.
Necropsy.

Brain: slight injection of cerebral vessels; dura not adherent; otherwise macroscopically negative, and no hemorrhage in the cortex.

Spinal cord: congestion of dura over dorsal region, extending down to the lumbar enlargement. Dura not adherent; no hemorrhage in the spinal cord itself; gray matter easily distinguished from surrounding white columns. Apparently no increase in cerebrospinal fluid.

Thorax: heart and lungs negative.

Abdomen: liver somewhat enlarged; otherwise negative; spleen, gastro-intestinal tract and kidneys negative.

Sections from spinal cord, cerebrum and medulla showed round-cell infiltration and some degeneration of anterior horn cells. Smears from the spinal cord, cerebrum and medulla proved to be too thick and nothing could be made out from them.

The brain and cord were stored in the ice-box in 50 per cent. glycerin.

February 24: Emulsion from cerebrum, medulla and spinal cord of the monkeys made in normal saline, filtered through gauze and then through Berkefeld and filtrate injected intraperitoneally in Monkey 2.

March 6: Monkey paralyzed in right hind paw. Temperature, 104.5 F.

March 8: Temperature, 103.2 F.

After this the monkey slowly improved and partially regained the use of its paw. It seemed in fairly good condition until April 19 or 20 when the upper extremities became involved. It was killed April 24.

Through a misunderstanding an assistant did a partial necropsy, removing the brain and cord, but macerating the cord so that sections could not be made. He said that the cord seemed very soft and that there was a great deal of fluid present, and also that there was something the matter with the lungs.

Impression smears of the brain stained with Giemsa showed a few extracellular and intracellular globoid bodies like those described by Noguchi.

April 10: Monkey injected intraperitoneally with filtrate made by passing through a Berkefeld filter an emulsion made up with normal saline solution of portions of the cord, medulla and cerebrum of the first positive monkey. Result negative.

May 8: Filtrate made by passing emulsion of remnants of spinal cord, medulla, etc., of the second positive monkey through Berkefeld filter was centrifuged and the upper portion injected intraperitoneally into a monkey with negative results.

SUMMARY

1. Negative results from feces of patient with typical poliomyelitis.
2. Positive result (paralysis and microscopic findings) from washings of nose and throat of patient with abortive case seventeen days after onset.
3. Positive result (paralysis and microscopic findings) of second monkey injected with brain and cord of monkey infected with washings.
4. Rapid loss of virulence of brain and cord.

THE QUANTITATIVE DETERMINATION OF ALBUMIN IN SPUTUM WITH POTASSIUM FERROCYANID *

M. L. HOLM, M.D.
State Bacteriologist
AND
L. R. HIMMELBERGER, B.S.
Assistant Bacteriologist
LANSING, MICH.

In summing up the annual records of sputa examinations in the past years it has been somewhat humiliating to realize that specific information has been given from the laboratory findings in only a little over one-fourth of the cases. The remaining three-fourths have been reported back negative, meaning that the patient may or may not have been afflicted with tuberculosis.

---

[2] Kling and Levaditi: Etudes sur la poliomyelitis aiguë epidémique, published by the Institut Pasteur de Paris, 1913.

* From the laboratory of the Michigan State Board of Health

The investigations of the albumin test during the past three years have inspired the laboratory worker with a new hope. The possibility of being able definitely to exclude tuberculosis by laboratory methods in a large proportion of cases is comforting, and the probability of giving valuable assistance in the diagnosis of incipient cases, while still closed, before the bacilli appear in the sputum is encouraging; but the additional announcement of a quantitative method and the presumptive relation between the percentage of albumin and progress of the case incites our fondest dreams.

Most workers who have investigated the albumin reaction are convinced that it is not receiving the attention it deserves.

In reviewing the literature we have been impressed with the comparative lack of uniformity in technic employed by different writers. Roger and Levy-Valensi diluted the sputum with equal volume of water, Lesieur and Prirez used one volume of sputum to four volumes of normal saline solution, and various other dilutions have been employed. Acetic acid, either quantity or strength not stated, has been used to coagulate the mucin. The method and reagents employed to determine the presence or absence of albumin are too numerous to mention. The personal equation in a test of this nature also is perhaps no small factor in producing variable results. In 1912, B. O. Works[1] proposed a quantitative method for determining albumin in sputum which is undoubtedly a step in the right direction. He coagulated the mucin in the sputum with 3 per cent. acetic acid, diluted to 33⅓ per cent. with distilled water, filtered and determined the albumin in an Esbach albuminometer. In our opinion the quantity of acetic acid should be specifically stated, as an insufficient quantity gives incomplete separation of mucus and an excessive quantity disintegrates the leukocytes and prevents proper separation of pus proteins. We also regard Esbach's reagent as an improper test for albumin in a mixture so complex as the average sputum. In many instances a precipitate is produced with this reagent when true albumin can be shown to be absent. Picric acid, the active ingredient of Esbach's solution, is a general alkaloid reagent. It precipitates with peptones, urates, creatinin and other bodies not affected by potassium ferrocyanid. Works found that his method gave albumin reaction with normal saliva, a fact we have repeatedly been able to confirm.

During the past two years we have been experimenting with a method for the quantitative determination of albumin which appears to give satisfactory results. A quantity of sputum, not less than 10 c.c., is collected in a dry receptacle in the usual way. (Samples containing blood should be rejected, as blood invariably contains albumin.) After smears for microscopic examination have been made a quantity of sputum not exceeding 10 c.c. is poured into a 50 c.c. graduated glass-stoppered cylinder. To this is added three times its volume of water containing 1 per cent. acetic acid, diluting the sputum to 25 per cent. After vigorous shaking with the stopper in place, the mixture is filtered through filter paper directly into a graduated centrifuge tube and 10 c.c. collected. To this are added 5 c.c. of 5 per cent. solution of potassium ferrocyanid in water and the tube whirled in a centrifuge for five minutes at average speed. The amount of albumin is most conveniently recorded in volume per cent., each 0.1 c.c. on the tube being 4 per cent. by volume after correcting for the original dilution. Absolute accuracy is impracticable in this work, so only approximate results should be recorded. If desired, the volume per cent. may be calculated to weight per cent. according to the method of Purdy for urinalysis.

At the time of this writing we have employed the above-described methods on something over five hundred sputa, including routine examinations and selected cases. The findings from 337 consecutive specimens taken in the summer and fall of 1913 are given in the accompanying table.

SPUTUM EXAMINATIONS

Tubercle Bacilli	Present	Absent
Albumin Reaction—		
Absent	1*	143
Below 2 per cent. by volume	6†	14 (1‡)
Between 2 and 5 per cent. by volume	4	16
Between 5 and 10 per cent. by vol.	6	24 (2‡) (1¶) (1§)
Between 10 and 25 per cent. by vol.	(1‡)28	34 (3‡) (2§)
Between 25 and 50 per cent. by vol.	34	13 (1‡) (1§)
Above 50 per cent. by volume	13	1
Totals	92	245

* Sample unsatisfactory. Patient died before another could be secured.

† Two were from improved cases. One showed both albumin and tubercle bacilli negative the following month. The other was lost track of Other four were mostly saliva.

‡ Contained blood.

¶ Case of pneumonia complicating pharyngeal diphtheria; adult.

§ Tubercle bacilli subsequently found.

Our experience indicates that potassium ferrocyanid when employed according to the method recommended does not produce a precipitate with normal saliva or gastric juice. Secretions from rhinitis, pharyngitis, bronchitis, asthma and other superficial inflammations of mucous membranes have given uniformly negative results. We have found many specimens of highly purulent sputum even with markedly disintegrated pus-cells to give absolutely negative albumin reaction by this method. On four occasions sputa have been examined shortly before and shortly after the first appearance of tubercle bacilli on microscopic examination, and the amount of albumin found to be substantially the same, indicating that the quantity of albumin is independent of the presence or absence of tubercle bacilli. Likewise, cases that have previously shown tubercle bacilli present have shown negative albumin and absence of tubercle bacilli with apparent recovery.

CONCLUSIONS

We agree with other workers that:

1. The presence of albumin in sputum indicates that it is not a superficial secretion but usually comes from some deep-seated inflammatory process.
2. Albumin is present in practically all sputa of tuberculous origin and that the amount bears some relation to the activity of the disease.
3. Persistent absence of albumin or its presence only in traces excludes tuberculosis as the source of that sputum. In our experience with the method described this is true in a large percentage of the cases examined.
4. The determination of albumin in sputum is one of the most important aids to the diagnosis and prognosis of tuberculosis that has been introduced in recent years. The simplicity of the method commends itself to the general practitioner as a routine office procedure. It is as easily carried out as is the determination of albumin in urine and is of greater importance.

A Social Ideal.—The substitution of solicitude for the race, as a motive, for desire for present and personal advantage, is the most important ethical product of civilization.—Henry B. Favill, M.D., in Louisville *Jour. Med. and Surg.*

THE DIET IN GASTRIC ULCER AND HYPERCHLORHYDRIA *

JOHN BENJAMIN NICHOLS, M.D.
WASHINGTON, D. C.

There are three main methods of treatment of gastric ulcer: (1) the surgical method, (2) the duodenal feeding method, and (3) the hygienic-dietetic-medicinal method, each having its own appropriate field of employment. The relative merits of these methods, and the considerations which guide in the selection of one of them in given cases, it is not proposed to discuss in this paper. Even if the surgical and duodenal methods possess advantages in the way of certainty and celerity of results, it is likely that there will always be patients who will decline or defer resort to these methods, or are so circumstanced as to necessitate a trial of ambulant treatment, or with whom for various reasons hygienic, dietetic, and medicinal treatment will be adopted.

In the medical treatment of gastric ulcer the necessary hygienic and medicinal measures may in importance equal or even exceed the dietetic regimen. Rest in bed, prolonged for a sufficient period, is especially of the greatest service and in many cases is absolutely essential to the attainment of a medical cure. Medicinal treatment, such as the use of astringents like bismuth or silver nitrate, of alkalies, of analgesics like orthoform or codein, and other remedies, is also an essential concomitant of the dietetic treatment. It is not purposed to consider those concomitant measures or the treatment of complications in this paper, which is to be devoted to a discussion of the physiologic and therapeutic principles that may guide to the selection of a rational diet in those cases of ulcer of the stomach and hyperchlorhydria in which this line of treatment is adopted.

A dietary regimen which has been extensively employed in this condition is that of Leub, more or less modified. This system begins with a period of fasting or great restriction of food, followed by gradual increase in the amounts given. Milk is the staple of this diet, along with soups and broths; eggs, carbohydrate food, and meat are gradually added later. The intervals between feedings recommended by different authorities range from as short as one hour up to several hours. The object of the restricted diet is to afford rest and freedom from irritation to the ulcer by minimizing gastric activity and dyspeptic conditions.

The dietary introduced by Lenhartz[1] in 1903 has also attracted much attention. This diet consists of milk and eggs, to which sugar, meat and carbohydrate food are early added. The daily amount of food is rapidly increased from a small allowance to an adequate maintenance ration. The object of this more ample regimen is to promote the general nutrition, while its abundant protein by entering into combination with the excessive hydrochloric acid of the gastric juice is supposed to neutralize or inactivate the latter.

Another diet, the fatty diet, has been introduced, but as yet has attained only a limited use.

It is my opinion (possibly presumptuous) that much of the current dietetic practice in gastric ulcer is based on fallacious grounds, and that a consideration of certain well-established physiologic facts will afford a definite guide to the adoption of a rational diet for this condition.

There are some factors in the causation and treatment of ulcers of the stomach corresponding to those of ulcers elsewhere; and some etiologic factors that are still obscure; but there is one factor peculiar to this condition that is of the utmost importance in its etiologic and therapeutic bearings, namely, the digestive properties of the gastric juice. Whatever the other determining conditions, it is clear that the corrosive action of the gastric secretion is a potent factor in producing and maintaining peptic ulcers. The high acidity characteristic of the gastric juice in cases of ulcer, whether it be cause or effect, is significant of this causative action. In addition to the indications that apply in the treatment of ulcers in general, such as rest, avoidance of irritation, promotion of nutrition, etc., we therefore have as a fundamental and peculiar object in the treatment of gastric ulcer the reduction to a minimum of the acidity and digestive power of the gastric juice.

The secretion, composition and potency of the gastric juice vary definitely and markedly under the influence of various dietetic conditions, thus enabling us to arrange a diet calculated to effect a maximum reduction of its elements.

Ordinarily gastric secretion takes place only in response to the ingestion of food. When there is no food in the stomach there is no gastric juice, and hence during the fasting period an ulcer would be free from its corrosive action. Duodenal feeding enables the gastric secretion to be thus suppressed for an indefinite period. Excepting by this method (rectal feeding being ineffective) intragastric alimentation can be dispensed with harmlessly only for a few days. In gastric ulcer a preliminary period of complete fasting can be carried out for a few days; when feeding is instituted, it seems rational that the intervals between feedings should be made as long as possible, in order to gain the longest practicable periods of freedom from the action of the gastric secretion.

After the ingestion of food, as shown by Pawlow,[2] the flow of gastric juice takes place in two stages and under two sets of influences; first, a flow starting immediately, due to psychic influences; and, second, another flow starting fifteen to forty-five minutes later, due to chemical stimulation (hormone action) by certain of the foodstuffs.

The psychic influences which initiate the flow of the gastric juice are the appetite and an eager desire for food. These influences act independently of the chemical character of the food taken, and may operate even in the absence of actual swallowing of food. Theoretically, therefore, it would be rather an advantage in treatment of gastric ulcer to employ articles of food that are not especially tempting or appetizing, as thereby a lessened primary flow of gastric juice is excited.

The secondary stimulation of gastric secretion, which begins about fifteen to forty-five minutes after the ingestion of the food, is dependent definitely and markedly on the chemical character of the food materials. Some foodstuffs greatly increase the amount and potency of the gastric juice secreted at this period, some lessen it, some are indifferent.

The substances which have been found active in stimulating the secondary flow of gastric juice are water, impure peptones, meat extractives and caffein. Water does not act in small amounts, but in quantities of 400 or 500 c.c. it evokes a considerable gastric secretion. Meat extractives, as in soups, broths, bouillon, beef tea,

[2] Pawlow, J. P.: Work of the Digestive Glands, second English ed., 1910.

meat juices, meat, etc., are active excitants of the flow of a potent gastric juice. The products of protein digestion also chemically excite secretion by the stomach; native proteins, such as white of egg, lack this power, but when their digestion is once started by the primary psychic or appetite juice, the digestive products so formed further stimulate secretion. Beverages and solutions containing caffein have been found by Moore and Allanson[3] to cause (in general) a marked increase in the hydrochloric acid content, total acidity, and digestive power of the gastric juice one hour after ingestion, as compared with the controls: coffee acted most strongly, tea next, cocoa least. According to Pawlow, soaps formed from fat in the food also stimulate gastric secretion.

The amount and duration of gastric secretion are of importance as well as the acid content and peptic power. In experiments on dogs Portis[4] found that on a meat diet the total amount of gastric juice secreted and the duration of the secreting period were three or four times as great as on a vegetable diet. Milk gave a time slightly longer than the vegetable diet, but much less than the meat feeding.

The bearings of these facts on the treatment of peptic ulcer are obvious. Water should be allowed in limited quantities only, not more than 250 c.c. (8 ounces, or one glass) at any one time. Coffee, tea and cocoa should be excluded. Soups and similar preparations rich in meat extractives from their lack of nutritive value are not only useless, but from their powerful stimulating effect on gastric secretion would seem to be absolutely contraindicated. Meat, it would seem, should be avoided, and protein food in general reduced to a minimum. The practice of giving protein food with the view of its neutralizing the gastric juice would appear to be fallacious and disadvantageous, since this kind of food causes a maximum flow and potency of gastric juice and increases the free hydrochloric acid, which will act on the ulcer as well as on the material that called it forth.

Some ingredients of the diet are without any specific chemical effect on gastric secretion, such as carbohydrate material. Ingestion of sodium chlorid or of hydrochloric acid causes no flow of gastric juice or increase of its hydrochloric-acid content (Floersheim[5]). Organic acids (acetic, citric, lactic, butyric) have been found (Foster and Lambert[6]) to cause *no increase of gastric secretion;* the acidity of fruits *would therefore not be objectionable* in gastric ulcer.

Among substances that inhibit gastric secretion may be mentioned sodium bicarbonate; weak solutions (0.05 to 1.0 per cent.) of this substance evoke no secretion of gastric juice in amounts that would be effective if water alone were taken.

The greatest practical importance in this respect attaches to the *influence of fat, which has been clearly* shown by Pawlow *and others to cause a marked lessening* of gastric secretion, as compared with meals otherwise *identical containing no fat.*

Pawlow[2] found that when meat is given one-half to one hour after introducing large amounts of olive oil into a dog's stomach, the primary psychic flow of gastric juice is abolished, and the subsequent gastric secretion is very much retarded and greatly diminished in amount and potency. A similar result is obtained when the fat is given immediately after the meat, except that the psychic flow begins in the usual five minutes, the inhibitory influence of the fat appearing later. The effect of the oil continues for two or three hours, after which an increase in gastric secretion may take place. The formation of soaps may produce a late stimulation of gastric secretion.

Moore and Ferguson[7] in comparative tests in sixty-one cases (including twenty-nine of peptic ulcer) found that *the total acidity, hydrochloric acid, and digestive power* of the gastric juice, determined one hour after eating, were in the general average reduced about one-third when the test-meals were preceded half an hour by an ounce of almond oil.

Cowie and Munson[8] in their investigations found that olive or cotton-seed oil given in quantities of one or more ounces half an hour before the meal as a rule caused a reduction (averaging about a third) of the hydrochloric acid and total acidity of the gastric juice (as determined after the usual test period of one hour). When the oil was given after or just before the feeding the effect was much less. The reduction corresponded to the quantity of oil given, larger amounts usually causing a greater inhibition. The oil delayed the beginning of the secretion of gastric juice, and retarded the height of secretion, so that although the acidity was less with oil after sixty minutes, it frequently increased later, often reaching a maximum as great as that of the control. The oil tended to retard the motility and evacuation of the stomach and prolong the period of digestion.

The fat content of milk also has an inhibitory effect on gastric secretion. Test-meals containing milk bring about the secretion of a gastric juice with a less hydrochloric acid content and lower peptic activity (after one hour) than meals containing the same amount of water instead. This effect is proportionate to the amount of fat in the milk; cream causes a greater reduction than whole milk, while skimmed milk is least effective (Pawlow[2]). The total acidity of the gastric contents after milk is, however, considerably greater than after other foods. This is apparently due to the lipolytic action of the gastric juice splitting the milk fat and setting free fatty acids, which increase the total acidity. The fat-splitting action of the gastric juice is most effective on fat in a state of fine subdivision (as in milk); it has little effect on fats or oils in bulk, which are very little changed in the stomach.

As to the way by which oil lessens peptic activity, Pawlow holds that it acts by reflex nervous inhibition of the secretory mechanism (as evidently occurs in the abolition of the psychic juice). Others believe that in addition there is some mechanical interference with the secretory stimulation caused by the oil forming a coating over the gastric mucosa and the food masses. Reflux of duodenal contents into the stomach has also been suggested as having some effect.

Other properties possessed by fat that are of importance *in connection with its use* in the dietary of gastric ulcer are: its high caloric value; its local sedative properties; its relaxing effect on pyloric spasm, and its laxative *action.*

Investigations of the inhibitory influence of drugs on gastric secretion have been very scanty. Portis[4] obtained little effect from scopolamin or opium; the only drugs

which he found effective were belladonna (especially before meals), and bromids (preferably in large doses and before eating, the strontium salt most effective). Hydrogen peroxid has been asserted by a number of observers to cause a reduction in hydrochloric acid secretion; it may be given in teaspoonful doses in a glass of water after meals, and is stated to be beneficial in hyperchlorhydria, though less so in ulcer (Hall[9]).

All the foregoing physiologic considerations have obvious, or at least theoretical, bearings on the dietetic treatment of both gastric ulcer and hyperchlorhydria, which may be thus summarized: The intervals between feedings should be made as long as possible, food being given preferably not more than two to four times a day. The diet should be as little appetizing, tempting and palatable as is practicable. Soups, broths and other preparations of meat extractives should be absolutely forbidden. Meat is to be excluded and protein food reduced. Coffee and tea should be avoided. Water should not be drunk in large amounts, not over 250 c.c. or 8 ounces at one time. Alkaline drinks, however, may be more freely taken. Carbohydrate food is permissible. Oil should be taken half an hour before meals, or the diet should contain a large amount of fatty material.

The fatty diet for gastric ulcer is grounded on these principles. While it has not yet come into extended use, the actual results obtained by those who have employed it have demonstrated its efficiency. No form of dietetic treatment will cure or ameliorate more than a certain proportion of ulcer cases; and good results are obtainable by diverse systems of feeding. There are no statistics by which the relative effectiveness of the fatty diet as compared with the Leube or Lenhartz methods can be estimated, but it is rational in theory and in practice it is capable of yielding satisfactory results in many cases.

In practice two forms of fat are mainly used, namely, (1) vegetable oils, such as olive oil, almond oil, cottonseed oil; and (2) milk fat, as in the form of cream.

In using vegetable oil, the best results would seem to be obtainable by giving it in quantities of an ounce or more a half hour before meals; with it is given a simple carbohydrate-fat diet. A number of writers have reported satisfactory results from this method. Oil thus given is, however, apt to become very tiresome and distasteful. As a variant method of administration it may be given made up in mayonnaise dressing, in which form it may be more acceptable and may be generously used as an ingredient of the diet.

The use of cream as the sole or chief ingredient of the diet is another plan that has found favor. The high caloric value of cream makes it one of the most valuable of dietetic articles for building up body weight and strength. One quart (four glasses) of cream a day yields about 1,800 calories, which alone is sufficient for many small-sized persons leading the quiet lives of invalids. (For a person weighing 100 pounds 1,800 calories is equivalent to 2,700 calories for a person of the standard wieght of 150 pounds.) A quart of cream, it is true, contains only about 25 gm. of protein; but 20 gm. more of protein would be furnished by the addition of, for instance, 600 c.c. of milk, or 220 gm. (six slices) of bread, or 230 gm. (five tablespoonfuls) of oatmeal gruel (cooked with milk), or three eggs. With cream as a basis an ample dietary can be arranged on which the body-weight will be maintained and even increased. The richness of cream in fat effects a marked inhibition of gastric secretion, and adapts it preeminently for use in peptic ulcer. Cream is less constipating than milk. It may cause acid gastric indigestion from the splitting of its fat by the lipolytic action of the gastric juice; but in my experience this troublesome effect usually disappears after a few days' persistence in the diet. Some patients cannot comfortably take cream as an exclusive and continued diet; yet in general it is better tolerated than might be expected, and if it causes no great disturbance there is no disadvantage in its not being especially relished. If not tolerated in full strength, the cream may be given diluted with an equal or greater amount of milk. The use of corresponding amounts of ice-cream in place of plain cream is a useful variant method of administration, which may be adopted *ad libitum;* and it is significant that unexpected benefit from the use of ice-cream in gastric ulcer was empirically noted before its physiologic rationale was elucidated.

My personal experience with the fatty diet in gastric ulcer covers about twenty-six cases. Not then aware of the published work along these lines, I was led by theoretical considerations to the conclusion that an abundance of fat with restriction of protein was the proper diet for this condition, and fixed on cream as a suitable foodstuff. In these cases cream was employed as the basic ration, ordinarily 1½ to 2 pints daily, divided into three or four feedings. Some patients were started with the full amount of cream, some with smaller amounts gradually increased, some with an initial fasting period. At first the cream was used alone; later were added cereal, bread, puddings, other vegetable food, eggs, etc.; oil (before or with meals), butter, mayonnaise dressing, and the like, were generously introduced into the dietary. Whenever desirable the cream was given diluted with milk, or in the form of ice-cream. Meat and soups were allowed last of all. The usual concomitant measures, such as rest in bed when feasible, astringents, alkalies, analgesics, etc., were employed as indicated.

During the first few days of the cream treatment troublesome dyspeptic symptoms (nausea, gas, acidity, etc.) often developed, frequently as severe as any the patients had ever experienced, and causing much discomfort and discouragement. This was probably due to the setting free of large amounts of fatty acids by gastric lipolysis. If the cream was persevered in these symptoms usually subsided, tolerance was established, and the diet was borne comfortably and contentedly.

The diversity of results characteristic of the treatment of gastric ulcer was observed in this series; some patients recovered, others were partially or temporarily relieved, some were unimproved. Some marked cases, including one with profuse repeated hemorrhages, progressed to good recovery, though two or three months or more of treatment, with many weeks in bed, were sometimes required to effect this result. The method is adapted to ambulant treatment, and seems a rational treatment for simple hyperchlorhydria as well as ulcer. It was also found to be of prophylactic service, as dyspeptic symptoms suggestive of recurrence of ulceration in treated cases usually promptly subsided after a few days' resort to cream diet. Although this series was too small for any very weighty deductions, the impression which I have formed of the results of the fatty diet has been favorable, and I believe that it is a rational and efficient method of dieting for gastric ulcer.

Beginnings of Modern Medicine.—There is not a single development, even the most advanced of contemporary medicine, which is not to be found in embryo in the medicine of the olden time.—Littré, Introduction to the Works of Hippocrates.

THE FOREIGN-BORN INSANE

A RACIAL STUDY OF THE PATIENTS ADMITTED TO THE INSANE DEPARTMENT OF THE PHILADELPHIA GENERAL HOSPITAL IN TEN YEARS (1903-1912)*

CHARLES W. BURR, M.D.
Professor of Mental Diseases, University of Pennsylvania, Department of Medicine
PHILADELPHIA

I purpose briefly to discuss the question of the alien insane in the United States using for data the number of native and foreign-born who were admitted to the insane department of the Philadelphia General Hospital (Blockley) during the decade from 1903 to 1912, inclusive. I should perhaps state that Blockley is the county hospital of Philadelphia, and that to its department for the insane are sent all indigent persons living in the city who become mentally ill, except a few who are admitted to the psychopathic wards (separate from the insane department in a legal sense, though situated on the same piece of land), and later deported or transferred to other hospitals without passing through the insane department. The number received in the psychopathic wards and not later transferred to the insane department is not large enough to influence the percentage to any great extent; but as my statistics are made up from the admissions to the insane department alone, the number of foreign indigent insane in the city is a little larger than my figures indicate.

There are also in the city two semipublic hospitals for the insane which receive, for short periods, a few charity patients, few of whom, however, are foreigners. These institutions receive a somewhat larger number of patients who are able to pay for a short time, but who are finally sent either to the Philadelphia General Hospital or to a state institution. It is alleged, but I personally know of only a few instances, that occasionally the relatives of immigrants who become ill soon after coming here send them to private institutions and support them long enough to make it practically impossible to deport them, unless they or their relatives desire it, which they never do, and then have them transferred to a state institution or to Blockley. Though some of the foreign-born insane at Blockley pay some board, the amount paid is so small and the number who pay so few that practically all may be regarded as indigent.

There are doubtless some mistakes in the statistics I present, but none of them leads to serious error in the conclusions drawn. Thus fifty patients are recorded as having been born in Poland, the recorder seemingly being of the opinion that Poland still flourishes as a political entity. The real explanation is that persons coming from either Russian or Austrian Poland, and less frequently those from German Poland, speak of themselves as Poles, and of course racially are such. In a few instances a man is credited to the country of his birth, though he does not belong to any of the races native to the country in which he happened to be born, and in a few others the mother was of one country and the father of another, in which case the paternal country is recorded. Some European countries, notably Russia, Austria and Germany, contain many races. In the hospital records only the country of birth is recorded, not the race. Hebrews are not recorded as such in the admission book, but only in the individual histories. They are here credited to the lands in which they were born. No attempt is made in this paper to distinguish the different races in any country, but all persons born in Germany are regarded as Germans, those born in Russia, Russians, and so on. All the errors of all kinds combined do not influence in any way the main conclusion that a startlingly large number, 44 per cent., of the indigent insane in the Philadelphia General Hospital are foreign-born. I have no statistics as to how many of them are politically aliens, that is, not citizens. No data are obtainable as to how long many of them have been in this country; but quite a large number, especially among the Irish, English and Germans, have been here many years, while most of the Russians, Italians, Roumanians and Hungarians are recent acquisitions.

The figures on which the paper is based are as follows: The total population of Philadelphia in 1900 was 1,293,696, and in 1910, 1,549,008. The foreign-born population in 1900 was 293,669, and in 1910 it was 382,578, of which 193,994 were males and 188,584 were females. The percentage of foreign-born in 1910 was 24.7; of white native-born, 69.8, and of negroes 5.5. The negro population in 1900 was 62,613; in 1910 it was: males 39,431 and females 45,028, making a total of 84,459.

The total (sane and insane) foreign-born population in 1900 and 1910 is given in Table 1 (I have omitted countries from which no or only a small number of insane persons came). It is noteworthy that the number of Irish, English and Germans decreased in the ten years. The falling off in the number of Chinese is not hard to understand. All the figures were taken from the thirteenth census of the United States.

TABLE 1.—SANE AND INSANE FOREIGN-BORN POPULATION IN 1900 AND 1910

Countries	1900	1910
Austria	6,893	19,859
China	1,165	997
England	36,726	36,530
Germany	73,040	61,467
Hungary	2,781	12,459
Ireland	98,385	85,187
Italy	17,829	45,308
Japan	12	93
Russia	33,111	90,696
Scotland	8,477	9,174
Sweden	2,143	2,420
Switzerland	1,707	2,013

The statistics concerning the insane admitted to the hospital are as follows: During the years 1903 to 1912, inclusive, there were admitted 4,897 males and 3,849 females, a total of 8,746. Of these, 2,052 were foreign males and 1,837 foreign females, making a total of 3,889 foreign-born patients, which is 44.5 per cent.

The foreign-born insane (excluding countries sending only a few) came from the countries given in Table 2.

TABLE 2.—THE FOREIGN-BORN INSANE

Countries	Males	Females	Total
Austria	111	75	186
England	162	142	304
Germany	429	315	744
Hungary	58	50	108
Ireland	499	741	1,240
Italy	187	114	301
Poland*	26	24	50
Roumania	14	17	31
Russia	306	251	557
Scotland	30	42	72
Sweden	17	16	33
Switzerland	23	12	35

* This includes Austrian, Russian and German Poland. Many Poles are listed under the country in which they were born. The country of birth of the fifty is unknown. Most of them probably are Russians.

---

* Read at the meeting of the Philadelphia Psychiatric Society, May 9, 1913.

The classification by color is given in Table 3. All persons known to have negro blood are recorded as negroes, even though there may be a large admixture of white blood.

TABLE 3.—CLASSIFICATION BY COLOR

Races	Males	Females	Total
Caucasians	4,421	3,412	7,833
Negroes	457	437	894
Mongolians	19	0	19

I have not given the table showing the number of patients from each foreign country admitted to the hospital each year of the decade, because it is not of enough value; but I wish to make some quotations from it. The yearly figures would be of great value if we knew the yearly fluctuations in population, not during the last ten only, but throughout the last fifty years; but the only dependable statistics we have are those of the United States census, which is decennial. There is no way of finding out the racial character of the population year by year. The tables of arrivals of immigrants by ship is of no value, because an unknown number immediately move to other places, and, on the other hand, an unknown number come here from other parts of this country.

It must be remembered that insanity occurs not only in recent immigrants, but also in foreigners who have lived here many years, though I have been much impressed of late years by the number of recent young immigrants who become insane; but I have no data concerning the percentage. There is no close relation between the number of immigrants from any given country in any one year and the number of insane from the same country admitted to Blockley in that year. Some conclusions, however, can be drawn from the yearly tables. Thus there were 22 men and 13 women admitted from Russia in 1903; in 1912 there were 42 men and 28 women. The number varied in the intervening years, but on the whole the curve tended upward. There has been a pretty constant increase in the Russian immigration each year, and, since the death-rate is less than the number of new arrivals, there has undoubtedly been a yearly increase in the number of Russian residents, so that it is natural that the number of the insane should increase.

When we consider Italy we find that while the number of its people living in Philadelphia increased from 17,829 in 1900 to 45,308 in 1910, the number of admissions to Blockley varied greatly from year to year, the greatest number being 44 in 1907, and the smallest, 24, in 1908. In 1912 there were 41.

England and Ireland, which represent an older layer of immigration than Russia or Italy, have pretty flat admission curves for the decade. In both instances the insanity curve will probably soon begin to fall, and then fall rapidly, unless, which is improbable, there should be a new wave of immigration from these countries.

Hungary, considering the small number of its people living here, makes a very bad showing—108 patients. Of course, however, in interpreting these figures it must be remembered there is no way of determining what percentage of the Hungarians who have lived in Philadelphia during the past ten years have become insane, because we do not know how many have lived here in that time; we only know the number for the first and tenth, but not the intervening years. I suspect, but am not sure, that quite a number of Hungarians living in other parts of the state, and indeed of the country, are sent to Philadelphia by their friends as soon as they show signs of becoming ill. This, in a small degree, decreases the percentage of the insane Hungarians in other counties and states, and correspondingly increases the rate in Philadelphia. As the same data are lacking for all countries we can properly draw conclusions as to certain matters concerning all, and in doing so, Hungary does not stand well. Russia gives the greatest number of all foreigners, sane and insane, living in the city in 1910; Ireland ranks second, and Germany third. Of the foreigners in the hospital, Ireland gives the greatest number, Germany is second and Russia third. I do not think that from this one can draw the conclusion that the Irish, under altered conditions of life in a foreign country, are more prone to insanity than the inhabitants of the Russian Empire. In the first place, the numbers we are dealing with are entirely too small to be of any use in the study of the racial frequency of disease, and in the second place, many Irish have lived here long enough to suffer from senile insanities, while the Russian is a newcomer, and the majority of immigrants from that country are still young.

The frequency of insanity in a race in its own home may be very different from that occurring in the same race in a foreign country, so that no conclusion can be drawn from my figures as to the relative susceptibility of different races in their home environment. The figures in Philadelphia are too small in any event, and even if we had accurate statistics covering the entire country, it would not be justifiable to draw conclusions as to racial susceptibility, except under the conditions in which the different races are now living. For example, I am quite sure, though I cannot prove it mathematically, that I have seen a large number of young Russian Jews in whom the exciting cause of disease was the total change in their environment: homesickness, inability to speak English, living in a large city instead of a small town or the country, the hurry of life and the intensity of work all act as exciting causes. Many of these persons, I believe, could, at home, have passed through life escaping all mental disease. It is, therefore, quite possible that the insanity-rate is higher among the Russian Jews here than in Russia. I am entirely incompetent to express an opinion as to whether or not the alleged persecution of Jews in Russia takes the place of the exciting causes of insanity existing here, and keeps the frequency of occurrence at the same level in both countries. Several races seem, however, to be mentally and emotionally much more adaptable to American life than the Russian Jew.

The important question for us as a nation is whether we should let things continue as they are or should do more than is being done to keep out the insane and to return to their native countries aliens who become insane. We are told by gentlemen who make political speeches in parts of the country in which there is a large foreign voting element that our national digestion is so strong that no evil can come by keeping our doors wide open for everybody. We hear much about being a haven for the oppressed, etc. We are told by the pessimists that we are "going to smash anyway," so there is no use doing anything. We are told by the disciples of "the uplift" that if we only send everybody to school and have plenty of laws to lift everybody up all evil will disappear. Probably none of these statements is true. Whether we can digest the foreigners or not, there is no reason why we should make our burden any heavier than we must. It is our duty to take care of the naturalized foreigner if he becomes unable to care for himself; it is his right as a citizen.

That we owe such duty to the alien no one believes, save those persons who have become so modern as to believe, and not only profess to believe, that it is our duty to relieve other people of their duty, a kind of morality which to the old-fashioned seems highly immoral and ultimately leading to degeneracy of the helped. If, however, an alien has been here for some years, has worked, and has in a sense become one of us, we ought, I presume, to care for him. To-day he cannot be deported if he has been here only a few years. Surely it would be better to deport all aliens who become insane within five years of their arrival, no matter what the cause.

I am told, whether correctly or not I do not know, that this would necessitate the abrogation of treaties with several countries; but if it be true, certainly we—who abrogated a treaty with Russia simply because she claimed the right of deciding what persons could pass her borders, a right which we ourselves claim and rigidly enforce when we want to, professedly on the highly sentimental ground that a certificate of American citizenship should open all doors—would be justified in abrogating treaties which compel us to take care of the mental wreckage properly belonging to other countries.

It is sometimes stated, but not proved, that since insanity is no more frequent among the foreigners than among the native-born we are no worse off by admitting and keeping them than if we refused to receive and expelled them. After all, it is said, healthy foreigners, by building up the country, pay for the upkeep of their insane. If it were not easily practicable largely to exclude the insane and degenerate, then of course it would be better to admit them than to prohibit all immigration. But that is not the question, because it is entirely possible to welcome the one while excluding the other. The fact still remains, no matter how much we may try to forget the inevitable effects, that in Philadelphia a foreign-born population of 21.7 per cent. supplies 44 per cent. of the indigent insane, and the same proportion approximately is found in all large asylums in all parts of the country to which immigrants go in large numbers.

1918 Spruce Street.

A CASE OF MULTIPLE SEROSITIS AND REPORT OF NECROPSY

WITH REMARKS ON TWO CASES, APPARENTLY EARLY INSTANCES OF THE SAME CONDITION

SOLOMON SOLIS COHEN, M.D.
Professor of Clinical Medicine, Jefferson Medical College, Physician to Jefferson Hospital and Philadelphia General Hospital

AND

R. MAX GOEPP, M.D.
Professor of Clinical Medicine, Philadelphia Polyclinic; Assistant Professor of Clinical Medicine, Jefferson Medical College; Assistant Physician to Jefferson Hospital and Philadelphia General Hospital

PHILADELPHIA

Of the many names that have been proposed for the condition discussed in this report, we have selected "multiple serositis," because it is descriptive and at the same time sufficiently short and convenient for practical purposes. A. O. J. Kelly, whose contributions on this subject are among the best in American literature, preferred the Greek term polyorrhymenitis (πολυς many + ὀρρος serum + ὑμην, membrane). "Malignant inflammation of serous membranes," or "Concato's disease," is open to criticism on account of the conventional association of the word "malignant" with a cancerous process, while some of the other designations, particularly "general chronic perihepatitis," "sugar-iced liver" (*Zuckergussleber*—Curschmann), "pericarditic pseudocirrhosis of the liver" (Pick's disease) are not sufficiently comprehensive and lay too much stress on the hepatic and pericardial features, to the neglect of the other serous membranes.

A convenient working classification divides the cases into (1) those exhibiting chiefly perihepatitis (Curschmann's *Zuckergussleber*), in which the peritoneum as a whole is the primary seat of disease; and (2) cases beginning as a pericarditis, in which the process spreads later to the peritoneum and may or may not involve the covering of the liver (Pick's pericarditic pseudocirrhosis, adherent pericardium). Clinically it is not usually possible to determine which organ was the primary seat of disease. In the case here reported, the pleural and peritoneal cavities were both extensively involved and there was also adhesive pericarditis. The symptoms, however, were predominantly cardiac, during the entire course of the malady, which extended over three years, and although this was in part owing to degenerative cardiovascular changes not necessarily connected with the serous membrane inflammations, the case may be classified in the pericarditic group. The report of the case follows:

History.—J. G., an unmarried Irish blacksmith, aged 43, was admitted to the wards of the Philadelphia General Hospital, Oct. 10, 1912. The chief complaint of the patient on admission was shortness of breath, cough, and swelling of the legs and abdomen. The patient bore all the marks of an alcoholic, and admitted having been a heavy drinker. He had had measles, mumps, whooping cough and smallpox. Eleven years before admission he had had an attack of rheumatism. Gonorrhea had been contracted about fifteen years before admission, and syphilis at some earlier time. No information of importance in regard to the family history was obtained. During the past thirteen years the patient was treated in the Philadelphia General Hospital eight different times, but had not, prior to the last admission, come under our observation. The dates of admission and discharge, and the recorded diagnoses, are as follows:

Jan. 5, 1904, to Feb. 1, 1904. Inflammation of penis and prepuce.

April 5, 1904, to April 11, 1904. Alcoholism.

Oct. 8, 1909, to Nov. 15, 1909. Pulmonary tuberculosis.

May 4, 1910, to June 28, 1910. Acute gastritis.

October 4, 1910, to June 26, 1911. Aortic regurgitation, mitral regurgitation, specific aortitis.

Sept. 8, 1911, to Sept. 27, 1911. Hepatic cirrhosis with ascites.

Oct. 9, 1911, to June 13, 1912. Aortic valvulitis, relative mitral regurgitation, cirrhosis.

Oct. 9, 1912, to Nov. 20, 1912. Multiple serositis and hypertrophic cardiac dilatation, aortic aneurysm or dilatation, relative aortic incompetence.

On admission to our service Oct. 9, 1912, the patient was orthopneic and markedly cyanotic. The abdomen was much distended with fluid, the legs and scrotum very edematous. The appetite was poor and the bowels were constipated. The patient complained of distress after eating, as if "all the food he took remained in the upper part of his belly." It seemed necessary to give prompt relief, and accordingly a trocar and cannula were inserted at the level of the umbilicus, about one inch to the right of the median line, the point for puncture being indicated by palpation which showed many adhesions and thickenings in the regions in which puncture is more usually made. One gallon of lemon yellow and somewhat cloudy fluid was withdrawn. Microscopic examination of this fluid showed chiefly lymphocytes, with a few endothelial cells. The tapping greatly abated the difficulty of breathing, and the patient was enabled to lie down for the time being.

Examination.—The patient is well developed and well nourished. The skin is cool and moist, the face is bluish. The pupils are equal, regular in outline and react normally to light and accommodation. The tongue is slightly coated and shows a fine tremor when extended. The ears and lips are deeply cyanosed. The external jugular vein on the left side is very large and tortuous, the right is also tortuous but smaller; there is no visible venous pulsation. The chest is fairly well developed. There is some flattening on the right side.

The upper border of the heart is in the second interspace, the right border 1.5 cm. to right of sternum, the left border 2 cm. to left of midclavicular line, the lower border extends to the sixth interspace. The apex beat is neither visible nor palpable. At the apex, the first sound is of good muscular quality and quite clear; the second sound is replaced by an indefinite murmur. At the aortic area, the first sound is accompanied by a very faint murmur, the second sound is accompanied or almost entirely replaced by a loud ringing and churning murmur, transmitted downward along the sternum, more clearly on the right than on the left. An area of dulness is demonstrated over the upper portion of the sternum from the clavicular junctions to the upper border of the heart, extending on the left to the parasternal line. No thrill is detected. The pulse is of the water hammer type, with fair force and volume; the tension of the artery is only moderate, but sclerosis of the wall is evident. The capillary pulse is visible in the nailbed.

Anteriorly, on the left side of the chest, the inspirations are labored and harsh, as though there were some pressure on the bronchi. The expirations are prolonged and of a bronchial character. Occasionally squeaking sounds are heard. The percussion note is impaired. As far as the third rib on the right side, the breath sounds are the same as on the left; below that point and in the axillary region of the same side, inspiration is harsh and accompanied by numerous moist râles of all sizes. Expiration is of the bronchial type. Both vocal resonance and fremitus are exaggerated, and the percussion note is dull. Posteriorly, on the left side, there are a few small moist râles in the lower part of the lung. Below the ninth rib the breath sounds are absent. Over the angle of the left scapula vocal resonance and tactile fremitus are more easily detected than at the corresponding area on the right side. The resonance of the left lung is slightly impaired. In the right lung there are numerous crepitant and subcrepitant râles, beginning a little below the apex, and extending as far down as the eighth rib. Below that point the breath sounds are absent and there is flatness on percussion. Vocal resonance and tactile fremitus are absent over the flat area, both are exaggerated where the râles are most numerous, especially at the inner border of the scapula. The percussion note is impaired above the flat area.

The abdomen is very much distended. Liver dulness extends from the fourth interspace to about two inches below the costal margin in the midclavicular line. Flatness on percussion (fluid) begins about 1½ inches above the umbilicus. The scrotum is very edematous. The lower extremities are greatly swollen and pit on pressure. The skin of the legs is reddened.

Course of Disease.—Soon after the tapping made on admission, the ascites recurred. October 22 the abdomen was tapped a second time, and 5 pints of fluid were withdrawn. October 24 the right side of the chest was aspirated, and 11 ounces of fluid were obtained. The first half of the fluid was of normal color, the second half was almost pure blood.

The temperature oscillated between 97.6 and 100 F., the pulse rate varied from 72 to 100, the respirations were 20 to 35. The urine showed nothing abnormal. The fluoroscopic examination showed considerable enlargement of the cardiac shadow, with a pulsating shadow above the heart, corresponding approximately with the dull area noted at the top of the sternum.

The patient's general condition remained about the same, with slight "ups and downs," and little, if at all, influenced by drugs for three weeks after admission. November 1 a chill occurred, followed by rise of temperature and pain in the right side of the chest. The temperature reached 102.6 F. Local applications relieved the pain. The next day percussion showed that the area of dulness over the right lung had extended to the angle of the scapula. A needle was inserted at this point and a few drops of blood were obtained, but nothing else. At the same time a third tapping of the abdomen 2 inches below the umbilicus and 2 inches to the left of the median line, yielded a quart of bloody fluid. The dyspnea was somewhat relieved by this procedure. About two weeks later a trocar and cannula were again inserted 2 inches below the umbilicus in the median line, and only a few drops of blood withdrawn. After removal of the cannula the opening bled quite freely.

Fever of an irregular type persisted all this time. The patient's general condition became steadily worse, he took less nourishment and rested badly. Cyanosis and dyspnea could not be materially relieved, although oxygen palliated them somewhat. Pulse, temperature and respiration continued irregular until death, which occurred suddenly on November 20.

Necropsy.—Dr. Allen G. Ellis found the following pathologic conditions:

The body is that of a well nourished adult man. Rigor mortis is present. There is great edema of the lower extremities.

The abdomen is markedly distended and contains about 500 c.c. of grayish turbid fluid. The peritoneum shows numerous adhesions, between coils of the intestines and the abdominal wall. Most are recent and are easily separated. Some adhesions, especially around the cecum, are older. The liver projects 5 cm. below the costal margin, its capsule is thickened and presents the typical "sugar ice" appearance. The chest is a mass of adhesions which includes both pleurae, except a little of the upper part of the left, the pericardium and the mediastinal tissues. The pericardial cavity is entirely obliterated by firm adhesions. The right pleural cavity is also obliterated.

The heart is greatly enlarged particularly on the left side. The left ventricular wall is 2 cm. thick, that of the right ventricle, 1 cm. thick. The muscle is rather pale and quite firm. The endocardium is grayish, the auriculoventricular valves show no notable change. The coronary arteries are moderately sclerotic. The aorta is entirely involved by necrotic, calcareous and atheromatous patches, the valves are incompetent. Just above the aortic valves is an aneurysm 4 cm. in diameter, which bulges about 3 cm.; at its apex is a further dilatation 1 cm. deep and 1.5 cm. wide. Above this, involving the great branches of the arch, is a second bulging, smaller and less sharply defined than the first. The pulmonary artery is atheromatous, the valves are not affected.

The left lung is markedly reddened. It is filled with serum. At the base it is tightly adherent and was torn in removal. Over the lower part of the upper lobe is a slight fibrinous exudate. The right lung shows a greatly thickened pleura. At the base, between it and the diaphragm, is a cavity bounded by greatly thickened brownish red pleura, which is rough on the internal surface. It is partly filled with bloody fluid. The lower lobe of the lung is atelectatic. The upper lobe is reddened and contains an excess of serum.

The spleen is 16 cm. long, firm, dark red on incision, and contains an excess of blood. The left kidney is large, the capsule tense. When it is stripped, a granular surface appears, the incised surface is dark bluish red, and blood drips from it. The cortex is not notably changed. The right kidney has a similar appearance. The ureters and bladder show no gross lesions. The stomach shows a dark red discoloration of the mucosa, particularly intense toward the pylorus. The liver is a rounded organ, 26 cm. long, 17 cm. wide. The capsule is very greatly thickened, at points it is cartilaginous in consistency. On incision the parenchyma presents a "nutmeg" appearance, also grayish areas of fibrous proliferation. The gall-bladder is not discernible. The pancreas shows no gross lesions.

Pathologic Diagnosis.—Hypertrophy of right and left ventricles of the heart: chronic adhesive pericarditis; atheroma of the aorta with multiple aneurysms; bilateral chronic adhesive pleuritis; acute fibrinous pleuritis in the left side; loculated hemorrhagic pleuritis at the base of the right lung; atelectasis of the lower lobe of the right lung; congestion of the spleen; cyanotic induration of the kidneys; congestion of the stomach; red atrophy and cirrhosis of the liver; chronic productive perihepatitis; chronic adhesive peritonitis, with added acute fibrinous peritonitis.

In regard to the etiology of multiple serositis it is worth noting that frequent association with arteriosclerosis and chronic interstitial nephritis has been observed. In view of the wide distribution of the lesions, affecting several or all of the serous membranes, the condition has been ascribed to the action of a toxin, analogous to that of anemia. On the other hand, a variety of pathogenic organisms, including, among others, *Bacillus typhosus, B. tuberculosis, Plasmodium malariae and Spirochaeta pallida*, have been held responsible. Association with tuberculosis has been noted frequently. The case presented might be cited in support of the theory of the syphilitic origin of multiple serositis. It is to be borne in mind, however, that the condition is essentially a terminal phenomenon, occurring usually in patients who have suffered for years from grave organic disease, and the existence of syphilis, tuberculosis or any of the other common diseases, might reasonably be viewed as a coincidence or as a predisposing condition rather than as the efficient cause of the specific changes in the serous membranes. Pathologically, the case presents most of the features that have been described as characteristic, and, as has been stated, may be assigned either to the peritoneal (perihepatic) or pericardial (adhesive pericarditis) group. The condition of the aorta is probably the result of syphilitic aortitis, and does not seem to be an essential feature of the polyorrhymenitis.

The affection, however, is not always a late development. Not far from the time that this case was under observation one of us (S. S. C.) had under care at the Jefferson Hospital a girl of 10 or 11 years who had developed, following scarlet fever, a tendency to recurrent exudations into the pericardium, pleurae and peritoneum. There was not sufficient impairment of the heart or kidney to support the diagnosis of passive effusion, due to failure of circulatory or excretory function. Both spleen and liver were enlarged and tender; there was hyperleukocytosis. Roentgen-ray examination showed enlargement and deepening of cardiac shadow and a dense mass of abdominal shadows, obscuring all details. Tuberculosis could not be excluded positively; neither could it be demonstrated beyond cavil, although the Moro test gave an affirmative result. The beginning of the exudative period was accompanied by fever, which subsided as the physical signs of fluid became marked. A period of prolonged quiescence occurred under treatment and the patient was removed from the hospital and the city. Her present condition is unknown.

Later, in the service of one of us (S. S. C.) also at Jefferson Hospital, a man of middle age, admitted with typhoid fever, developed inflammatory pleural and peritoneal effusions, which necessitated tapping, and which recurred twice during the prolonged convalescence. The liver, spleen and heart gave no evidence of involvement.

It is possible, even plausible, that these two cases—of which fuller report will be made later—represent one of the modes of origin of multiple serositis; namely, as an epiphenomenon of infections; but under what exciting conditions, in the absence of a recognized specific organism, it is difficult, if not impossible, to say.

A further allusion may be made to the remarkable condition of the aorta in the subject of the main report of this paper. Dulness over the upper part and to the left of the sternum, with the peculiar churning murmur heard in this region, led to the suspicion of aneurysm or of considerable aortic dilatation with a relative insufficiency. This opinion was confirmed by the large pulsating shadow shown on the fluoroscopic examination; but the multiplicity of the aneurysmal sacs was not suspected.

SIGNED CONSENT TO A NECROPSY A CONDITION TO ADMISSION TO OUR HOSPITALS

A BRIEF ACCOUNT OF TEN YEARS' EXPERIENCE IN THE PHIPPS INSTITUTE OF PHILADELPHIA

H. R. M. LANDIS, M.D.
Director of the Medical and Sociologic Departments of the Phipps Institute of the University of Pennsylvania; Assistant Professor of Medicine in the University of Pennsylvania
PHILADELPHIA

The following account has been written to show how one hospital has solved the problem of the need of American hospitals for more necropsies, discussed recently by Theodore C. Janeway.[1] Whether or not the plan of requiring a signed consent to a necropsy in case of death is feasible for all hospitals, I am not prepared to say. I do feel, however, that the plan can be adopted far more generally than is at present thought possible, if the medical profession as a whole will take a more active interest in the matter.

It is an undeniable fact that far too many of the attending physicians and surgeons in our hospitals are lukewarm in their attitude toward this question, while most physicians without hospital connections take little or no interest at all. For those who are interested both in the advancement of the art of medicine and in the more thorough equipment of our students, it is rather discouraging to learn from the figures quoted by Dr. Janeway that, with three or four exceptions, only from 4.8 to 24.5 per cent. of the dead in our institutions are examined post mortem. The handicap under which American investigators and teachers labor is made more apparent when it is realized that in Germany and Austria the percentage of necropsies ranges from 77 to 99.9; in England from 71.9 to 85.9, and in the two great hospitals of Montreal from 62 to 86.4. As Dr. Janeway has well said, there is "no factor at the moment which operates so strongly to discourage careful clinical investigation in the wards of our hospitals as the probability that for three-quarters of the patients studied, the results will be lost in the case of death by failure to secure an autopsy."

It was just this realization of the situation that led to the adoption of compulsory necropsies in the Phipps Institute at the time of its organization ten years ago. The first director, Dr. Lawrence F. Flick, realizing that the staff of the institute would have to be trained in the diagnosis of diseases of the chest, and that a thorough study of the pathology of tuberculosis was possible only through the performance of as many necropsies as possible, made admission to the wards of the institute conditional on the signing of a blank reading as follows:

---

[1] Janeway, Theodore C.: The Great Need of American Hospitals: More Autopsies, Mod. Hosp., October, 1913.

> I, ———, being the nearest responsible relative of M ———, in consideration of treatment and care at the Henry Phipps Institute, for the Study, Treatment and Prevention of Tuberculosis, do hereby grant permission to the medical staff, in event of death at that institution, for a necropsy.
>
> I will also be responsible for the removal of the body.
>
> Witness .... Signed ....
> Address .... Address ....

The accompanying table shows the number of patients treated in the wards, the number of deaths and the number of necropsies.

HOSPITAL PATIENTS, DEATHS AND NECROPSIES

	In Hospital	Deaths	*Necropsies*
1903	238	54	53
1904	234	89	89
1905	197	60	60
1906	205	69	69
1907	227	80	78
1908	195	53	53
1909	225	76	75
1910*	108	51	49
1911	122	40	38
1912	121	42	40
	1,872	614	604 or 98.37 per cent.

* The decrease in the number of patients and necropsies is due to the fact that in the spring of 1910 the bed capacity of the institute was reduced from 52 to 24, with 2 emergency beds.

In the ten cases in which no necropsy was held, it may be said that the right to do it was not waived because of objections raised after the death of the patient. In but one instance was there any probability that the family would have tried to resist the institute in the exercise of its rights.

For the first seven years the institute maintained fifty-two beds for advanced cases only. In the spring of 1910, when it was transferred to the University of Pennsylvania, the number of beds was reduced to twenty-four with two emergency beds. Finally, when the new Phipps Institute was opened in May, 1913, but half the twenty-four beds were devoted to advanced cases, the other twelve being used for incipient cases.

Although there is little likelihood of any of the latter patients dying in the institute, the same requirement is exacted for admission to the incipient as to the advanced ward. Even in the case of patients admitted but for a few days for some special treatment the necropsy blank must be signed.

The question naturally arises: To what extent has the signing of the necropsy blank militated against persons entering the institute? With the possible exception of Jewish patients, it practically has had no influence whatever. While no record has been kept of families who refused to allow a relative to enter the institute on account of this requirement, I can safely say that the number of refusals has been negligible and that there has never been a time when there was not a waiting list.

Etiology of Mental Disease.—The problem of the causes of mental diseases is perhaps the one most subject to the influence of prejudices on account of its still being wrapped in obscurity and because it involves the vexed enigma of the relation between mind and body, between consciousness and organic cerebral processes.—Lugaro, Problems of Psychiatry.

COUGH-DILATATION TIME A MEASURE OF HEART FUNCTION

PRELIMINARY NOTE *

JAMES BIRNEY GUTHRIE, B.S., M.D.
Professor of Clinical Medicine, Tulane University of Louisiana, Medical Department
NEW ORLEANS

For a number of years I have been an exponent of the light percussion method of outlining the heart borders. On one occasion, after having carefully outlined the heart of a patient in bed, who was suffering with a marked degree of cardiac insufficiency, and having drawn on the chest-wall a projection diagram, I was interrupted for a few minutes; and then I returned and repeated the procedure. To my surprise, I found that the outline had changed, and that the right heart border was pushed out 2 cm. Investigation as to the cause of this phenomenon showed that the patient had coughed rather violently in the interval, and in so doing had dilated the heart. This patient I regarded then as having a most interesting and unusual case of heart weakness. A number of my colleagues, who, like myself, were interested in the light percussion method, were brought in to see this case, and concurred with me as to the existence of *cough dilatation.* The dilatation reached its maximum after three cough efforts, and in this particular case lasted five minutes, during which time there was a gradual return to the original outline.

For some time I believed that this case, and similar ones which I found subsequently, were extreme cases of cardiac weakness. I discovered them in a colored service made up largely of cardiorenal cases. This view, in the light of subsequent work, I no longer hold, but have come to look on the procedure of outlining the heart by percussion or roentgenoscopy before and after cough, timing the return to the original size of the outline, as a most valuable index of the integrity of the heart muscle. The healthy heart dilates on coughing to a degree perceptible during Roentgen examination, but not appreciable by percussion. The time factor is quite as important as the measurement of the outward displacement of the right heart border. The graver the heart weakness, the longer the dilatation lasts. The longest cough-dilatation time observed so far has been fifteen minutes, and the shortest five seconds. This statement is based on careful examination of over one hundred cases. It is probable that this range of cough-dilatation time will be extended on further observation.

It is evident that any effort (such as straining at stool, sneezing or other expulsive respiratory effort) which involves the closure of the glottis, and a more or less prolonged straining with the muscles of forcible respiration, raises intrathoracic pressure, and narrows every radicle of the pulmonary artery. The resistance is thus increased, and the response of the heart muscle to this purposely set task of coughing is observed in a rapid cough-dilatation, after which the heart may either return immediately to its normal size, or the cough-dilatation may last fifteen minutes.

I have often found that patients who could not be taught to cough vigorously could be made to bring about the same result by holding the nose and trying to force out the breath with the mouth closed. This pushes out the borders of the whole right ventricle very promptly, and accomplishes what the three successive coughs do, and in less time. This effort, similar to horn-blowing, the patient makes readily, and the timing of cough-dilatation may commence as soon as free respiration begins again.

---

* Presented before the Mississippi Valley Medical Association, at New Orleans, Oct. 24, 1913.

A search through the literature fails to reveal a single test of heart function which involves a systematic observation of the heart-change resulting from a designed alteration in the resistance in the pulmonary circulation. Either percussion, orthodiagraph, ordinary fluoroscope or roentgenograph may be used to determine the variations in the position and shape of the heart borders during cough-dilatation. The left heart border also is to be observed before and after coughing, and the outline changes as does the outline of the right heart border, but returns to resting position a few seconds earlier. This phenomenon of the pushing out of the left border is due, I believe, entirely to the dilatation of the right ventricle. In practice it is hardly necessary to observe the cough-dilatation time on both heart borders, the observation of the right being quite sufficient. There are some practitioners, however, who find difficulty in percussing the right heart border, and who seem to be fairly successful in outlining the left. These might find it necessary to make observations entirely on the left heart border, but would have to bear in mind that there would probably be some cases of moderate dilatation (that is, moderate heart weakness), which would be missed if the changes in position of the right border during the cough-dilatation time were not studied along with those of the left.

Timing the duration of these changes is the most important observation. In addition, by auscultation at the second left inter-space after coughing, a variation can sometimes be detected in the intensity of the second pulmonic sound during cough-dilatation. This variation has not been studied thoroughly, but will probably be found to vary as does the blood-pressure in Katzenstein's test of the left ventricle (simultaneous digital compression of both femoral arteries just below Poupart's ligament). The effect on pulse-rate is also a subject for future work.

The actual distance from the midsternal line that the heart borders are pushed outward by cough or by the horn-blowing procedure I at first regarded as the most important phase of the test; but I now look on the reaction time (cough-dilatation time) as the most important single factor. As I now use it, the test consists in measuring the horizontal distance between the resting position and the heart borders after cough or after forcing the breath, as in horn-blowing, together with the time necessary for the heart to return to resting position after cough-dilatation — that is, reaction time.

I do not expect corroborative results from any one who does not use the light percussion method. I do not believe that it is possible to obtain correct heart outlines, except through using the lightest percussion blow with the minimal force necessary to produce sound waves over resonant structures. One who uses heavy percussion must fall back on the orthodiagraph or fluoroscope in studying the cough-dilatation time.

The advantages of this method are its simplicity, the ease with which it can be done, and the fact that elaborate, costly apparatus is not necessary in order to carry it out. A watch, preferably a stop-watch, a skin-pencil and a centimeter tape-measure constitute all the apparatus necessary.

While it cannot be asserted for any procedure which brings on a dilatation of the right ventricle that it is absolutely free from danger to the patient, the three successive coughs, or a single horn-blowing effort with mouth closed, sufficient in my experience to bring on maximum dilatation, have never caused any disastrous results to the patient. These three coughs given at a word of command hardly call for more effort than the patient himself makes innumerable times without direction from the physician.

As to the surgical aspects of this test, it would seem from present knowledge that it would be hazardous to operate under general anesthesia on a patient who had a cough-dilatation time as great as five minutes. Further investigation will probably force the conclusion that the danger-line lies considerably below five minutes. I have seen several safely operated on who showed positive cough-dilatation, but whose cough-dilatation time was less than one minute. Some one has tersely remarked that it is not the patient with known cardiac disease that dies from anesthesia, but the one in whom it is not suspected. The use of this test during the examination previous to operation will, I believe, help to put into the "known" category some cases that ordinarily would escape the usual methods of heart diagnosis.

From the point of view of therapeutics, this work shows wherein lies one of the grave dangers to the cardiac patient. Dilatation can be demonstrated coming on in a very weak heart after a single act of coughing, and after any muscular effort performed with the glottis closed, such as lifting, stooping, straining at stool, getting into and out of bed, blowing a wind instrument, etc. With the exception, perhaps, of cough, all of these are comparatively easy for a cardiac patient to avoid. Cough in cardiacs must be treated, if the strain on the right ventricle is not to be multiplied indefinitely. The study of these various cough-dilatation phenomena suggests the inference that here is to be found the chief explanation of the benefit derived from opiates in cardiac insufficiency.

I am not of the opinion that in this test we have arrived at the Ultima Thule of heart investigation, or that it will prove more useful than any of the other tests hitherto devised; but I do believe that it will be found to supplement the tests of the left heart already known, and that in a number of cases it will be the first obtainable sign of heart weakness. If one can obtain an approximate idea of the integrity of the heart muscle in a ventricular wall, it may be fairly assumed that the other portions of the heart will show the same proportion of normal fibers.

A RAPID METHOD OF ISOLATING PATHOGENIC STREPTOCOCCI FROM CONTAMINATED FIELDS

LOUIS L. TEN BROECK, M.D.
MINNEAPOLIS

The work of Sabouraud in demonstrating the streptococcus in skin lesions, the bacteriology of which had been misconstrued; the researches of Rosenow, Hamburger, Capps, Davis and others in giving this germ an important place as a causative factor in epidemics; Billing's writings on the remote effects of focal infections; Rosenow's contributions to the study of rheumatism, and his interesting experiences in the mutability of the streptococcus when grown under varied conditions, have greatly increased the importance of study of this organism and especially stimulated study in methods of isolation and differentiation. Notably among these are the studies of Gordon, Walker and others in fermentation tests, and Ruediger's suggestion of differentiation by hemolysis.

For a long time there has been wanted a method of rapid isolation of this germ from such badly contaminated fields as the nasal and respiratory passages, neglected phlegmon, etc., which at the same time would clearly establish its pathogenic properties in a way that morphologic or cultural phenomena could only indirectly accomplish.

My attention was first drawn to this subject during a friendly discussion with a well-known rhinologist who was removing a turbinate for the relief of an intractable asthma. It was argued that persistent nasal infections were far more frequently streptococcal than supposed; that asthmatic complications were in part at least a condition of allergy in which the streptococcus took a very prominent part, and that the reason why this germ was overlooked was because of deficient bacteriologic technic. It was agreed to call in a competent bacteriologist for the usual cultural examination and at the same time attempt to devise a method for the demonstration of the streptococcus. Accordingly the bacteriologist reported only the *Micrococcus catarrhalis*. The special technic devised was based on the following principles:

1. Use of liquid mediums as suggested by Sabouraud.
2. Extreme susceptibility of rabbits to streptococci.
3. Peculiar reaction and vulnerability of the peritoneum to streptococcal infections as described by Murphy. It was thought that by grading the dose the peritoneum would fall a prey to the streptococcus even before the other pathogens took hold, and that a certain point of the disease would be reached when there would be the characteristic dry peritonitis or retroperitoneal cellulitis. Intraperitoneal injections of from 2 to 5 c.c. of fresh bouillon cultures of a mixed growth (obtained by dropping the thoroughly washed resected bone into bouillon) were made every two or three hours. At the earliest signs of sepsis the animal was chloroformed and a dry peritonitis was found yielding pure and intensely virulent cultures of streptococcus.

The vaccine prepared by the bacteriologist was impotent. That from the peritoneal exudate was not only helpful in the asthmatic condition, but reduced the blood-pressure from 175 mm. to 145 mm. This method has been used in four cases of subcutaneous infection, in all of which the diversified bacteriologic flora had misled the attendants and in which the method not alone promptly cleared up the diagnosis but was made the basis for proper immunologic measures that provoked a very gratifying response.

I believe that in these cases, in all of which the usual measures had been exhausted without relief, this method saved a human life. In another case there was a fatal issue. This patient died before a diagnosis even was established.

It is not suggested that this method be used to the exclusion of others. It is to be used in conjunction with other approved methods. Neither is it to be expected that there will always be a pure streptococcic culture to the exclusion of other pathogens, but the peculiar reaction will help establish the diagnosis; and the more virulent the streptococcus, in which case greater haste and certainty is demanded, the more certain will be the result. In persistent postnasal infections, I have been able to find this germ by first using negative pressure to draw from the deep sinuses, and then, having the patient swallow (to isolate the posterior nares), I have changed from negative to positive pressure, opening the other nostril. A stream of air in this way is forced into one nostril and out of the other and can be directed into suitable mediums. The colonies on solid mediums are for the most part discrete and are derived from the posterior nares just as well as from the anterior, a result impossible to attain by any method requiring use of a swab.

Since writing the foregoing, I find that Cole has used a similar method in isolating the pneumococci from sputum, injecting the same intraperitoneally into a rat, which animal meets the needs of the pneumococcus better than any other. Rabbits are usable, however, and as a rule are more readily obtainable. The method is therefore not a new one, but it can be applied in any laboratory, and its use will undoubtedly unmask the real bacteriologic cause of virulent or persistent infections, and with the present status of immunotherapy will also not infrequently assist in effecting a cure.

CHRONIC MALIGNANT DEGENERATION OF THE THYROID

WITH REPORT OF CASE

FRANK A. CARMICHAEL, M.D.
OSAWATOMIE, KAN.

Malignant degeneration of the thyroid is not uncommon in itself. Both sarcoma and carcinoma occur in this gland with such frequency that the subject of malignancy as a whole affecting this structure would cover a very wide scope. There have been noted, however, certain cases of malignancy of the thyroid pursuing a remarkably chronic course, of which very little has been written, so far as I have been able to determine from a reasonably painstaking search of the literature of the past few years.

This unusual type presents some striking variations from the ordinary types of malignant change in marked aberrations from the usual trend of malignant neoplastic growths of the same general character in other anatomic locations, and a behavior of morbid tissues at variance with that of the same cell type under similar conditions of proliferative excitation in tissues in close physiologic and anatomic relationship to the thyroid. This peculiarity seems to be confined to a certain type of growth springing from the epithelial or glandular elements of the thyroid and is not manifested in the various sarcomatous degenerations that affect it.

From time to time mention has been made of the unusual chronicity of certain types of malignant adenoma of the thyroid by various writers. This feature of extreme chronicity in carcinomas of the glandular type in a gland of such actively secretive and metabolic importance as the thyroid, with its unusually ample blood and lymphatic supply, constitutes an anomaly that may, so far as I am aware, be accounted for only on hypothetic grounds.

Whether this unusual chronicity may be attributed to an inhibitory influence of the normal colloid substance of the gland, or to the iodin content of the gland secretion, or to some peculiarity inherent in the parent tissue cell, has not so far been clearly determined; yet the phenomena of neoplasms of the adenocarcinomatous type extending over periods of from five to fifteen years is occasionally noted. The pronounced tendency of thyroid malignancy to metastasize in the osseous structure and the frequent extremely slow course of their development in these locations tends to strengthen the hypothesis that in the peculiarity of the cell itself or in that of its complex secretions we may find the solution of the problem of this chronicity.

It being a well-defined law applicable to all neoplasms that metastases must partake of the cell form and structural characteristics of the parent growth, the inference by analogy is that they must also conform in rate of growth and development with that of the primary tumor.

It has been stated that great difficulty is frequently encountered in the microscopic determination of the nature of these growths because of the alteration of tissue by infiltration of connective tissue or chronic inflammatory changes that so obscure the findings that many fields and many sections must frequently be examined before anything resembling adenomatous structure is discovered. This may doubtless account for the various departures from the ordinary nomenclature in relation to the gross or microscopic appearance of these growths in the reports of various writers.

We may thus construe the "iron-hard struma" of Reidel as a carcinoma of atypical form, its ligenous character dependent on connective-tissue infiltration, while the "chronic malignant strumitis" recently reported by Meyer[1] might be accepted as a type of carcinoma or other malignant field on which some inflammatory process, bacterial or toxic, has been engrafted.

Perhaps the most interesting phenomenon in connection with these cases of chronic malignant change is that we are forced to the assumption of the ability of the neoplastic cell to assume the secretive function of the normal glandular structure. This assumption has its support from the fact that in careful microscopic examination of certain of these glands when the patient had exhibited no symptoms of thyroid insufficiency, no traces of glandular structure even remotely approaching normal could be found.

Von Bergmann reports a case in a man past 40 in whom, after removal of the thyroid for carcinoma, symptoms of myxedema promptly appeared, continuing until a recurrence, when they gradually subsided as the recurrence became more marked. Two years later the entire growth was removed because of pressure symptoms, when tetany immediately developed.

Von Eiselsberg reports a similar case with identical symptoms following a primary and secondary operation.

While this must be accepted as presumptive evidence that neoplastic cells may take on the function of actively secreting structures, thereby invalidating the definitive clause applying to neoplastic growths "without function," it is not conclusive, as we cannot feel assured that aberrant parathyroids were not removed in the second operation. This, however, does not alter or modify the significance of the phenomenon of myxedema developing on the primary extirpation of the gland, with the subsidence of symptoms on the development of metastases.

The clinical features of the case which I shall report confirm in a measure the observations of von Bergmann and von Eiselsberg in so far as they relate to the systemic disturbance incident to the removal of the primary tumor.

REPORT OF CASE

The patient, J. E., farmer, aged 50, born in England, came to America as a boy. Family history is negative as to tumor growths, goiter, tuberculosis or syphilis; father, six brothers and four sisters are living. Patient has always been healthy though never robust; thinks he has had the common diseases of infancy, but no illness or injury since attaining manhood. He denies any form of venereal infection. At the age of 15 he noted a small nodule in the region of the thyroid which within a year attained the size of a walnut. From this time until about eight years ago it remained practically stationary. In 1907 it began to increase rapidly in size, forming a large, moderately soft, pedunculated mass, and within a year became so large that it was necessary to support it by suspending it from the neck with a very large handkerchief.

On the advice of his family physician he went to Chicago, where the entire tumor mass was removed. The entire right lobe, isthmus and major portion of the left lobe were removed. Healing was by first intention. Immediately following the operation there were slight trismus, mental hebetude, dryness of the skin and other evidences of incipient myxedema, which gradually disappeared on the development of a recurrence. Within a week after operation there was a noticeable increase in the size of the fragment of left lobe, which rapidly increased to the size of a tangerine, forming a brawny infiltrating mass. *Six months later a metastasis appeared on the manubrium*, which has gradually increased in size. Contrary to the rule, there has been no pain or edema in either the primary or the secondary tumor. Patient eats, sleeps and feels well. There is a slight laryngeal cough.

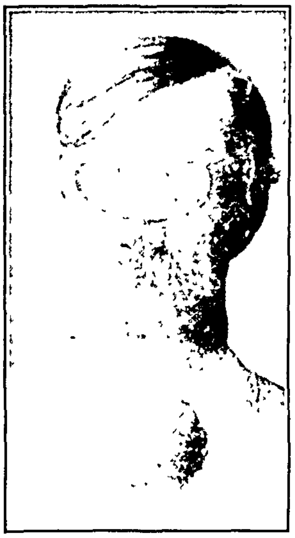

Fig. 1.—Malignant degeneration of the thyroid as it appeared in January, 1909, two years after operation.

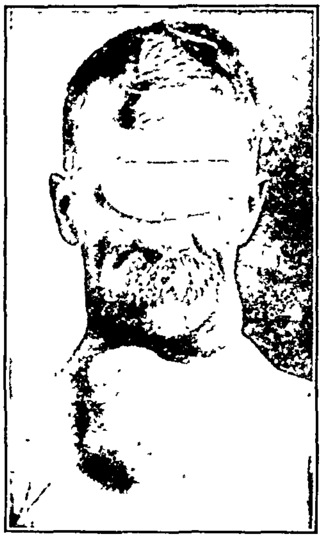

Fig. 2.—Appearance of growth in July, 1913.

Examination shows a man fairly well nourished, thin but not cachectic, muscles fairly firm, skin elastic and of good color, eyes, chest, abdomen and reflexes normal; temperature normal, pulse 76. The supraclavicular, infraclavicular and axillary lymph-nodes on the left side are enlarged and fixed to the underlying tissues, enlargement being most noticeable in the supraclavicular group. A large sessile tumor occupies the site of the left thyroid lobe. A large, nodular and extremely hard tumor mass, the size of a child's head, covers the manubrium and a part of the gladiolus. These tumors are fixed, painless and of unusual hardness. The superficial veins over the sternal tumor mass are enlarged, tortuous and prominent.

Our knowledge of the etiology of these growths does not extend beyond those factors favoring malignancy elsewhere in the body. Erhardt accepts the view that the chronic irritation accompanying goitrous changes with their attendant local vascular alterations is responsible for most cases, which is supported by the fact that malignant degenerations, when they occur, almost invariably occur in thyroids that have undergone goitrous changes.

---

[1] Meyer: Chronic Malignant Thyreoiditis, Peculiar Granuloma Consisting of Eosinophils and Plasma-Cells Originating in the Right Lobe of the Thyroid, Ztschr. f. Path., 1913, xii, 116; abstr., Surg., Gynec. and Obst., 1913, xvi, 362.

Braun, Cramer, von Eiselsberg, Halstead and others attribute a certain causative rôle to trauma.

The feature claiming special interest in these cases, however, is the extreme chronicity of certain types of carcinoma of this gland. The course of sarcomatous changes in the thyroid does not materially differ from that of its occurrence elsewhere in the body. Most carcinomas also run their course within the usual two- or three-year limit. Pathologists are emphatic in their contention that the occurrence of scirrhous growths in the thyroid is extremely rare, and yet we find certain malignant changes essentially of the adenocarcinomatous type that pursue an extremely chronic course extending over a period of many years, so insidious in their growth and development that they were not considered malignant by earlier writers, who even characterized their metastases as "benign metastases."

Claiming equal interest and offering a promising field for research is the problem of whether or not a neoplastic cell originating in a functionating gland may take up and perform the functions of its normal secreting structure.

A CASE OF PATENT DUCTUS ARTERIOSUS (BOTALLI)

WITH REPORT OF A NEW PHYSICAL SIGN

IRVING SIMONS, B.S., M.D.
NASHVILLE, TENN.

The comparative rarity of patent ductus arteriosus and its diagnosis during life has been attested by the comparatively infrequent reports. In this case the diagnosis seemed clear even without the roentgenogram, which simply affirmed the clinical findings, although there are unquestionably many cases which need the roentgenogram for diagnosis.

The presence of Frank's sign (that is, audibility of the murmur in the left interscapular space), and its presence on the right side also, is worthy of mention. The lack of pulsation of the shadow of the pulmonic artery is to be noted also as Wessler and Bass state that this pulsation is pathognomic.

CASE-REPORT

C. O., aged 21, white man, born by normal delivery, not a blue baby, was a healthy and normal child, except that he has always been deaf and dumb; has had measles. There is no history of rheumatism except for occasional attacks of stiff neck. At the age of 13, while at school, he was noted for his ability as a football player. Once during this time he was confined to bed for two weeks with extreme dyspnea and fever (?) and his physician said he had heart disease and advised him never to play football again, but he continued to play. No symptoms of cardiac decompensation at any other time. Two months ago he had gonorrhea and developed epididymitis on the right side which is now quiescent.

Physical Examination.—General condition, good; spare, athletic young man. Heart inspection shows a very marked apical impulse diffused over the fifth and sixth spaces just outside of the midclavicular line.

Percussion shows right border normal except below, where it sweeps outward a couple of fingers beyond the sternum (4 cm. from the midline). Cardiohepatic angle of 90 degrees. Liver percusses dull at fifth, flat at sixth space.

Left border shows marked dulness at base of heart in the second and third left spaces. Apex in fifth and sixth spaces in anterior axillary line.

Measurements of left border:

In first space— 6.5 cm. from midsternum.
In second space— 7. cm. from midsternum.
In third space— 9.5 cm. from midsternum.
In fourth space—11. cm. from midsternum.
In fifth space—12. cm. from midsternum.
In sixth space—12.5 cm. from midsternum.

Palpation shows a continuous purring thrill in the second left space extending downward even to the third left space. It corresponds to the area of dulness described above and its position is shown on the illustration by the mark X.

The apex-beat is very forcible and extends over the fifth and sixth spaces and the sixth rib. Its position is shown in the illustration by a circle, the point of maximum intensity being represented by a dot in the circle.

Auscultation shows a loud rumbling continuous murmur heard over the second and third left spaces, X. This murmur is absolutely continuous but has a systolic and diastolic exacerbation, of which the former is the louder. It is not transmitted anywhere over the front of the thorax, or up the carotid arteries, nor is it heard in the radials or the femorals. It corresponds to the thrill felt and described.

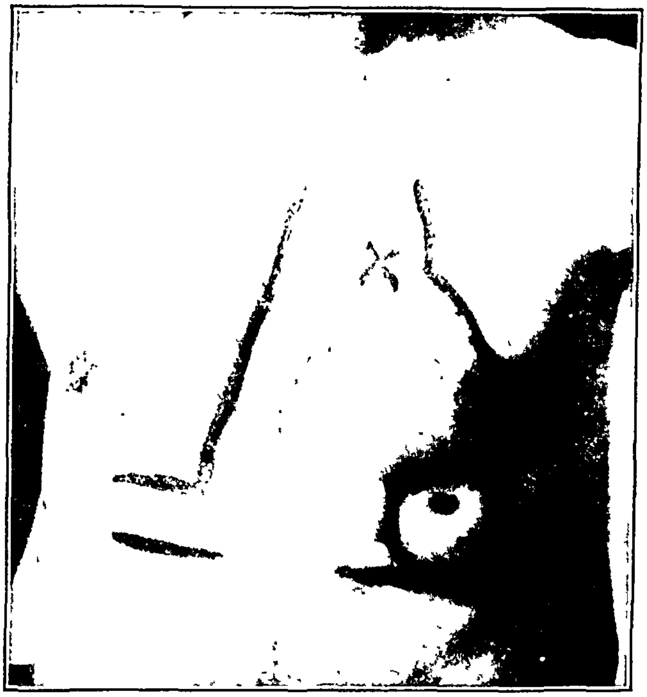

Diagram illustrating the position of the thrill murmur and the cardiac borders.

The second pulmonic sound is not distinguishable. The second aortic is clear and distinct. In the back it is heard on both sides in the region between the scapulae and the vertebral column at about the level of the spine of the scapula. Here it is heard on both sides but fainter on the right side than on the left. The sounds are, of course, markedly diminished as compared with the sounds heard anteriorly.

At the apex is a soft non-transmitted systolic murmur. The pulses are equal, regular, of normal rate and synchronous. No collapsing quality noted.

Blood-pressure: (auscultatory method).
Systolic, 105 mm. Hg.
Diastolic, 70 mm. Hg.

Extremities: Negative. No edema or signs of clubbing of the fingers or toes.

The rest of the physical examination is negative. The patient is in good health and does a moderate amount of heavy lifting in his work. Recently he ran up two flights of steps with me and was no more dyspneic than anyone without cardiac lesion would have been.

SUMMARY

The following features are noteworthy:

1. No distinct history of rheumatism.

2. A continuous murmur with thrill in the second and third left spaces, and dulness over these spaces for from 7 to 9.5 cm. to the left of the median line.

3. Localization of the murmur in both interscapular regions.

4. Left-sided cardiac hypertrophy.

5. Absence of discomfort due to heart except for one period of two weeks about eight years ago when he seemed to have some cardiac dyspnea.

A consideration of some of these observations leads me to a diagnosis of patent ductus arteriosus (Botalli). The dulness to the left of the sternum (Gerhardt's sign),[1] was well substantiated by the enlargement of the pulmonic artery which was shown in the roentgenogram. The localization of the murmur in the left interscapular region (François Frank's sign[2]) was clear.

The localization of the murmur in the right interscapular region has to my knowledge never been noted. If this localization is due to transmission down the pulmonic arteries, which would seem probable, there is no reason why it should not be bilateral.

The pulsation of the enlarged pulmonic artery, described as pathognomonic by Wessler and Bass,[3] was looked for with the Roentgen ray but was not observed.

The cause of the left ventricular cardiac hypertrophy is not at all clear. It may be due to aortic stenosis which is at times associated with open ductus arteriosus but there was no enlargement of the first portion of the aorta in the roentgenogram, as was shown in Wessler and Bass' fourth case.

There was slight enlargement to the right but the great hypertrophy of the left ventricle prevented the development of the round heart (*Kugelherz*) of Groedel.[4]

132 Eighth Avenue North.

A PREVIOUSLY UNEMPHASIZED FEATURE IN THE CONSTRUCTION OF NITROUS OXID-OXYGEN-ETHER APPARATUS

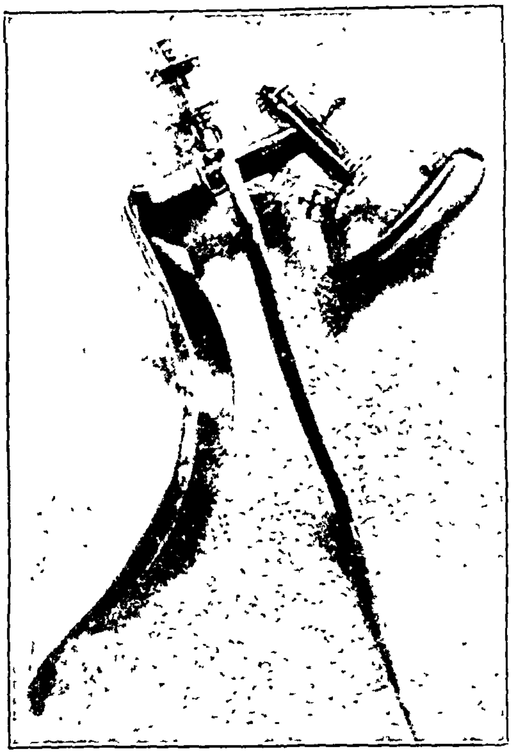
PALUEL J. FLAGG, M.D.
Anesthetist to The Woman's Hospital, New York, and St. Joseph's Hospital, Yonkers, N. Y.
NEW YORK

The usual arrangement of the various elements of nitrous oxid-oxygen apparatus are as follows: Nearest the face is the face-piece of variable size, shape and composition; next to this, a tube varying from 4 to 5 inches to 3 feet in length, and lastly, one or more bags used as a reservoir or for rebreathing purposes. These three elements, face-piece, connecting tube and bag, make up the essential parts of the nitrous oxid-oxygen apparatus.

Ether is dropped directly into this system, vaporizing therein before inhalation, or is admitted into the system previously vaporized.

Almost without exception the nitrous oxid and oxygen have been admitted, separately or together, directly into the bag, and it has been urged that a complete mixing be encouraged before inhalation is allowed. Many have gone so far as to provide definite percentages of nitrous oxid and oxygen. By this means it was thought possible to secure results which would not vary.

From a theoretical point of view this seems entirely satisfactory, but from a practical point of view the following difficulty arises: Imagine a person anesthetized. The anesthetist fills his bag with a definite mixture of nitrous oxid and oxygen. After the bag has been half emptied by the patient the operator finds that he has been mistaken in his percentages. The patient may either show symptoms of coming out or may be becoming rapidly cyanosed. In the first case concentrated nitrous oxid is demanded; in the second concentrated oxygen. The operator immediately runs in either nitrous oxid or oxygen, but he does not obtain the desired result because he must work through the half emptied bag, which serves to dilute the newly admitted gases.



Apparatus, showing tube for gas and oxygen entering apparatus near face-piece.

In other words, the apparatus is inelastic. It cannot adapt itself to the evanescent symptoms produced by the anesthetic. Many amateur failures of anesthesia by nitrous oxid-oxygen may be traced to this inelastic feature of the apparatus. The inexperienced, very naturally, cannot always guess what percentage to use, each patient being a law unto himself. If too much oxygen is used at the beginning, the patient refuses to go under; if too little oxygen is used, cyanosis or, in children particularly, jactitation occurs. The anesthetist can neither subdue in the one nor relieve in the other while there is still a residue in the rebreathing bag. After considerable disturbance on the part of the patient and anxiety on that of the anesthetist, an anesthesia fairly satisfactory to all concerned may be induced. Frequently the combination of a refractory patient, irritable, impatient surgeon and inexperienced anesthetist result in a poor form of gas-ether anesthesia, and gas-oxygen is blamed, unfairly, perhaps, but impersonally.

[4] Groedel: Deutsch. Arch. f. klin. Med, 1911, ciii, 413.

If the apparatus had been made sensitive, that is, if the nitrous oxid effects could have been had in concentrated form for only two breaths, the anesthetic state would have come on quickly. On the other hand, if oxygen could have been supplied at the first symptom of jactitation the anesthesia would have been far different.

The solution of the difficulty is so simple that its application can be made to any apparatus. The nitrous oxid and the oxygen should be admitted near the face-piece, proximal to the mixing-chamber. The gases when thus admitted flow back into the bag or are respired directly as desired.

If the gas is admitted during *an inspiration*, the patient receives it in concentrated form; if during expiration, the gas admitted is carried along with the expired air into the rebreathing chamber. When the gas is shut off the rebreathing continues as usual.

The effects of concentrated oxygen may be obtained by simply allowing it to run slowly and continuously into the apparatus.

To my knowledge, concentrated oxygen never did harm.

Concentrated nitrous oxid is required only in a light anesthetic state; that is, when the nitrous oxid content in the circulation is low. This state of light anesthesia is not likely to be confounded with any other condition, for there is no general depression as in ether. There is usually active light reflex, lid reflex, muscular rigidity and some movement, depending on the shallowness of the anesthesia.

In addition to this, it requires several respirations to saturate the alveolar capillaries with nitrous oxid, even when absolutely pure gas is used. But in my case the contents of the rebreathing bag tend to dilute the nitrous oxid admitted, thereby giving a high percentage of nitrous oxid rather than an absolutely pure nitrous oxid. The rate of diffusion of gases depends on their relative densities; the greater the difference in densities the greater the rapidity of diffusion. Consequently the warm gas in the bag and the cold gas just admitted diffuse rapidly.

Furthermore, there appears to be no clinical evidence that nitrous oxid thus administered is in any way injurious.

The apparatus used by me at the Woman's Hospital *illustrates this feature.*

This apparatus is a modification of the S. S. White inhaler. This inhaler is machine made, with interchangeable parts. A transparent celluloid face-piece enables one to watch the patient closely. The apparatus is always taken down after each operation and can be thoroughly cleansed and sterilized. Only one valve is used, a simple disk made of mica. The weight of the apparatus is two-thirds of Bennet's apparatus. It can also be used for a simple gas-ether anesthesia or for gas-oxygen induction followed by gas-ether.

The use of standard parts requiring small modification makes it possible to put out this device complete, including the rubber goods, bag and tubing, for the sum of twenty-five dollars.

The principle emphasized by Dr. R. C. Coburn in the location of the bag and also the position of the ether-cup have been employed, and acknowledgment is here made for many valuable suggestions gathered from the writings and remarks of Dr. Coburn.

120 Central Park South.

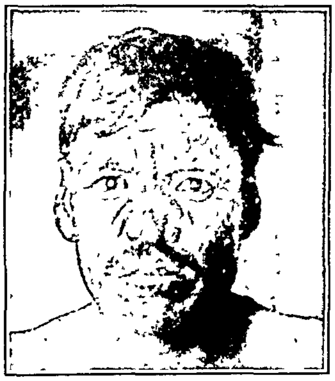
A CASE OF MACULOTUBERCULAR LEPROSY

W. R. Jamieson, M.D., El Paso, Tex.

History.—P. M., a Mexican of Indian type, aged 40, married, but for two years past separated from his wife, was referred, June 6, 1913, by Dr. J. E. Keltner.

The patient was born in Chihuahua, Mexico, and lived there until he came to El Paso eight years ago. During this time he was employed as a laborer and grave-digger at a local cemetery. Seven years ago he had rheumatic pains in his legs, accompanied with fever and swelling. He was unable to work for ten months. In the summer of 1911 he had fever, chills and rheumatic pains, which again appeared in May, 1912. Shortly after this two papules appeared on the forehead between the eyebrows; then for seven months there were no further symptoms. During this time he drank to excess. Five months ago new lesions began to appear, first on the face, then on the body. The patient says that recurrent crops of macules began to appear, successively taking up more surface and gradually becoming infiltrated and nodular. He lives with his father, mother and sister, none of whom present any symptoms of the disease.

Examination.—The patient is a well-nourished man of powerful build, with typical leonine cast of countenance. The forehead, nose and ears are studded with tubercles. Each nipple has one or two nodules. On the posterior surface of the upper arm are two infiltrated macular patches, about 6 by 3 inches in size, which are hotter to the touch than the sourrounding tissue and apparently are not anesthetic. The wrists and backs of the hands have pigmented spots, macules and a few nodules; the elbows and knees exhibit a psoriasiform eruption. The scrotum is so studded with tubercles that the eruption has an almost confluent appearance, while a few scattered nodules are on the penis. The lower limbs from the knees downward have pigmented spots, macular patches and a few scattered nodules. There is no ulceration anywhere. The heat-center is disturbed, as the patient perspires continually, particularly about the face, even when in a cool place.



Patient with maculotubercular form of leprosy.

The man was referred to Dr. L. B. Auerbach for *examination of the nose and throat, who reports as follows: The* cartilaginous septum is perforated in many places; the bony septum is crumbling, producing the typical saddle-nose. There is considerable crusting and discharge with an atrophic rhinitis. The turbinates are destroyed. The hard and soft palates are infiltrated with nodules. The uvula appears as a coarsely nodular and ulcerating mass, and seems to be sloughing. The tongue is irregular and nodular. The epiglottis, larynx, ary-epiglottic folds and ventricular bands are infiltrated, nodular, ulcerated and contracted. Nodules resembling papillomas are in various parts of the larynx. The pharynx, larynx and post-nasal space are all anesthetic. The voice is husky and snuffling.

Dr. W. W. Waite, bacteriologist of the Crouse laboratories, found typical lepra bacilli in the secretion from an incised nodule.

The patient was quarantined, but evidently becoming alarmed at the interest displayed in his case, decamped, and has not since been seen.

The Prepared Mind.—"In the fields of observation," said Pasteur, in his inaugural address as dean of the scientific faculty at Lille, "chance only favors the mind that is prepared."—G. T. Wrench, Lord Lister, His Life and Work.

New Instruments and Suggestions

DESCRIPTION OF AN APPARATUS FOR INTRATRACHEAL INSUFFLATION

J. P. Pratt, M.D., Baltimore

Intratracheal insufflation as a method of anesthesia is now well established. It has already been the means of saving lives as well as increasing the possibilities of surgery. It is unnecessary to deal here with the advantages and disadvantages of this method, as they have been discussed sufficiently in recent medical literature. An anesthetist to do the best work must be able to devote most of his time and attention to the patient, and his efficiency is decreased in proportion to the attention demanded by the apparatus used.

The apparatus here described is simple in construction and easy to manipulate.

The type of motor and pump used is almost noiseless. When the apparatus is in use it is well to have a foot-bellows near by in the event that the motor should fail to work properly. The three inlet tubes (F, F′ and the one to the right of F′) are therefore arranged so that the connection with the pump may be retained intact while the bellows is being connected. Instead of a bellows a tank of nitrous oxid or of oxygen may be employed.

The ether container, as already noted, is provided with a pressure equalizer. Were it not for this equalizer, the ether would be driven back into the container when pressure is admitted from below. The installation of the equalizing tube allows the ether to drop at the constant rate desired. This method of introducing the ether into the air-current has the following advantages: (1) any concentration of ether desired can be obtained; (2) the concentration is readily controlled; (3) an accurate idea of the amount of ether being used at any moment can be obtained by looking at the sight-feed.

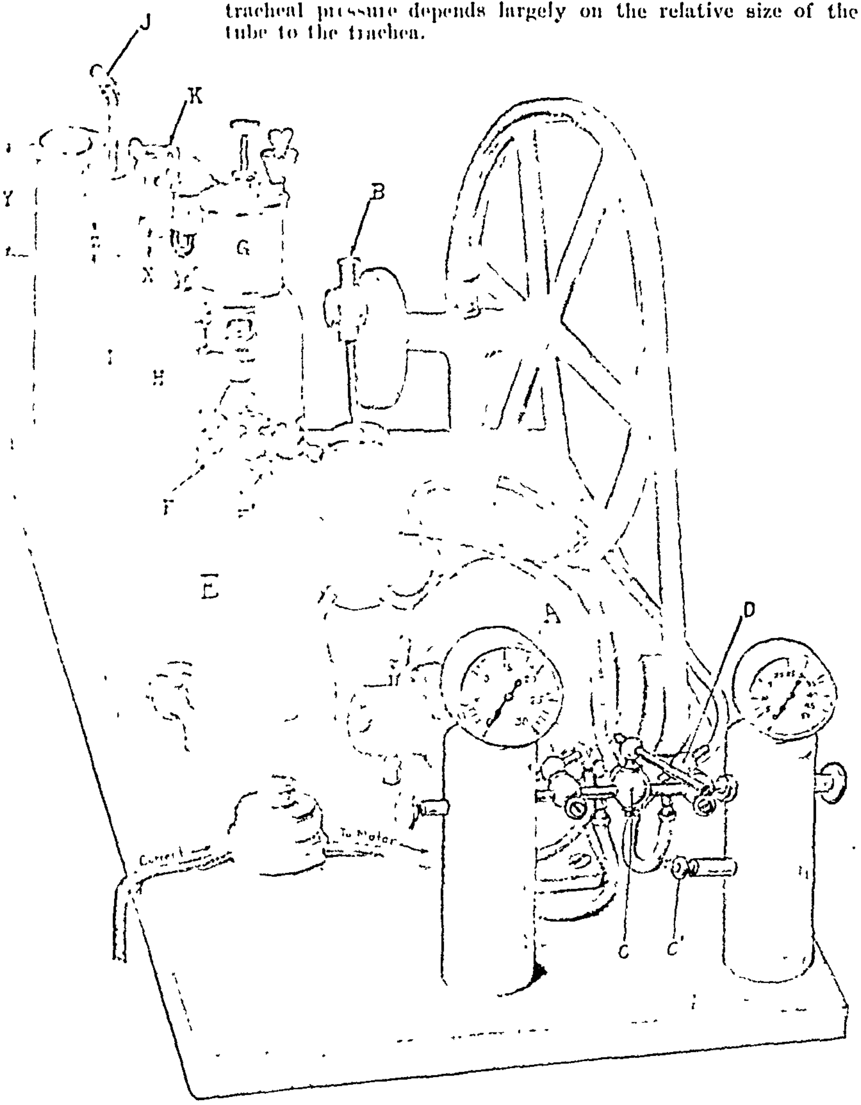
The ether driven by the current of air is vaporized in the warm coil and as it passes over the surface of the water it becomes saturated with moisture. Only a minimal amount of ether is absorbed by the water during the anesthesia, when the ether supply to the coil is discontinued, therefore, the flow of ether vapor into the tracheal tube promptly ceases. It is to be emphasized that the purpose of using warm water about the coil is solely to vaporize the ether. No attempt is made to warm the vapor, as the futility of such endeavors has been clearly demonstrated.

Furthermore, the passage of the vapor-laden air through the wide chamber above the water completely prevents the possibility of driving liquid ether into the tracheal tube.

A safety-valve is essential to an apparatus for intratracheal insufflation as emphasized by Melzer, and a manometer is also desirable in such an apparatus. Both have been provided in the machine here described, and for the sake of simplicity the two have been combined.

A glass tube is bent to form an elongated letter *S*. It is then so placed that one end opens into the air-space of the tank (*E*), and the other end is molded to form a cup which is covered with cotton and a perforated metal cap. The calibration arbitrarily chosen is that the distance (*X*) from the base of the cup to the concavity of the first curve shall be 2 cm. Into the manometer (*K*), mounted as shown in Figure 1, mercury is poured until (*Z*) the level of it in the arm (*Y*) is at the level of the base of the cup.

With the restoration of the initial pressure the mercury will flow from the cup into the tube and the manometer will be reestablished. When there is change of pressure in the tank, it will cause a rise or a fall of the mercury in the tube (*Y*). The fluctuations of the level of mercury thus serve as an indicator of the pressure of the current of air blown into the trachea, and grossly indicate the character of the respiration. If for any reason the pressure becomes greater than 2 cm. Hg, the mercury from the tube will be forced into the cup and the air will escape until the excess of pressure is relieved. The tube is not graduated, for apparently it is not necessary to measure accurately the machine pressure. Eisenbrey[1] has shown that with a machine pressure of 50 mm. Hg the pressure in the *trachea may* be as low as 2.2 *mm. Hg.* The intratracheal pressure depends largely on the relative size of the tube to the trachea.



Apparatus for intratracheal insufflation: A, an electric motor, 0.1 h.p.; B, a piston pump with valves at C and D; C′, a "spring-valve" to regulate the pressure of the stream of air; E: a metal tank nearly filled with warm water to vaporize the ether and to more completely saturate the air with moisture. F and F′ are inlets for the current of air, nitrous oxid and oxygen. They are connected with a copper coil placed in E, and the outlet of this coil is at the surface of the warm water near F. G is the container for ether with a sight-feed at H and a narrow tube (I) to equalize the pressure at the upper level of the ether with that of the air-current. J is the tube through which the anesthetic enters the trachea K is a combined mercury manometer and safety-valve.

The safety-valve as described is satisfactory when the apparatus is used in anesthetizing patients in whom the chest wall is intact. When, however, the thorax is opened, no dependence is to be placed on records of machine pressure. The guide must be the condition of the exposed lung.

For an intratracheal tube a woven linen or silk catheter is used. This tube is introduced into the trachea through a Jackson pharyngoscope by direct inspection of the larynx. The procedure of introducing the tube is very simple.

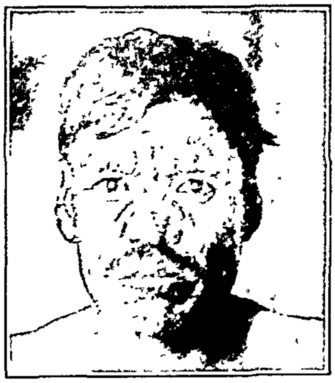
A CASE OF MACULOTUBERCULAR LEPROSY

W. R. Jamieson, M.D., El Paso, Tex.

History.—P. M., a Mexican of Indian type, aged 40, married, but for two years past separated from his wife, was referred, June 6, 1913, by Dr. J. E. Keltner.

The patient was born in Chihuahua, Mexico, and lived there until he came to El Paso eight years ago. During this time he was employed as a laborer and grave-digger at a local cemetery. Seven years ago he had rheumatic pains in his legs, accompanied with fever and swelling. He was unable to work for ten months. In the summer of 1911 he had fever, chills and rheumatic pains, which again appeared in May, 1912. Shortly after this two papules appeared on the forehead between the eyebrows; then for seven months there were no further symptoms. During this time he drank to excess. Five months ago new lesions began to appear, first on the face, then on the body. The patient says that recurrent crops of macules began to appear, successively taking up more surface and gradually becoming infiltrated and nodular. He lives with his father, mother and sister, none of whom present any symptoms of the disease.

Examination.—The patient is a well-nourished man of powerful build, with typical leonine cast of countenance. The forehead, nose and ears are studded with tubercles. Each nipple has one or two nodules. On the posterior surface of the upper arm are two infiltrated macular patches, about 6 by 3 inches in size, which are hotter to the touch than the surrounding tissue and apparently are not anesthetic. The wrists and backs of the hands have pigmented spots, macules and a few nodules; the elbows and knees exhibit a psoriasiform eruption. The scrotum is so studded with tubercles that the eruption has an almost confluent appearance, while a few scattered nodules are on the penis. The lower limbs from the knees downward have pigmented spots, macular patches and a few scattered nodules. There is no ulceration anywhere. The heat-center is disturbed, as the patient perspires continually, particularly about the face, even when in a cool place.



Patient with maculotubercular form of leprosy.

The man was referred to Dr. L. B. Auerbach for examination of the nose and throat, who reports as follows: The cartilaginous septum is perforated in many places; the bony septum is crumbling, producing the typical saddle-nose. There is considerable crusting and discharge with an atrophic rhinitis. The turbinates are destroyed. The hard and soft palates are infiltrated with nodules. The uvula appears as a coarsely nodular and ulcerating mass, and seems to be sloughing. The tongue is irregular and nodular. The epiglottis, larynx, ary-epiglottic folds and ventricular bands are infiltrated, nodular, ulcerated and contracted. Nodules resembling papillomas are in various parts of the larynx. The pharynx, larynx and post-nasal space are all anesthetic. The voice is husky and snuffling.

Dr. W. W. Waite, bacteriologist of the Crouse laboratories, found typical lepra bacilli in the secretion from an incised nodule.

The patient was quarantined, but evidently becoming alarmed at the interest displayed in his case, decamped, and has not since been seen.

The Prepared Mind.—"In the fields of observation," said Pasteur, in his inaugural address as dean of the scientific faculty at Lille, "chance only favors the mind that is prepared."—G. T. Wrench, Lord Lister, His Life and Work.

New Instruments and Suggestions

DESCRIPTION OF AN APPARATUS FOR INTRATRACHEAL INSUFFLATION

J. P. Pratt, M.D., Baltimore

Intratracheal insufflation as a method of anesthesia is now well established. It has already been the means of saving lives as well as increasing the possibilities of surgery. It is unnecessary to deal here with the advantages and disadvantages of this method, as they have been discussed sufficiently in recent medical literature. An anesthetist to do the best work must be able to devote most of his time and attention to the patient, and his efficiency is decreased in proportion to the attention demanded by the apparatus used.

The apparatus here described is simple in construction and easy to manipulate.

The type of motor and pump used is almost noiseless. When the apparatus is in use it is well to have a foot bellows near by in the event that the motor should fail to work properly. The three inlet tubes (F, F' and the one to the right of F') are therefore arranged so that the connection with the pump may be retained intact while the bellows is being connected. Instead of a bellows a tank of nitrous oxid or of oxygen may be employed.

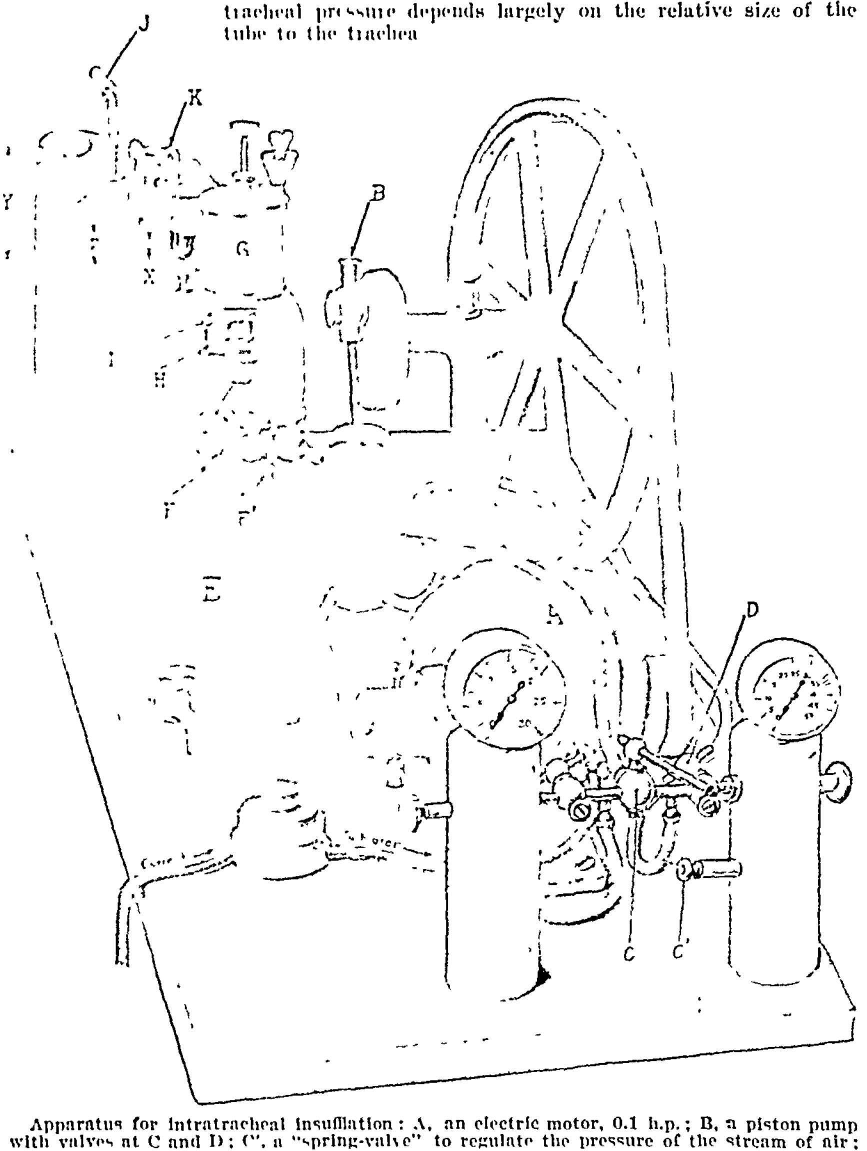
The ether container, as already noted, is provided with a pressure equalizer. Were it not for this equalizer, the ether would be driven back into the container when pressure is admitted from below. The installation of the equalizing tube allows the ether to drop at the constant rate desired. This method of introducing the ether into the air-current has the following advantages: (1) any concentration of ether desired can be obtained; (2) the concentration is readily controlled; (3) an accurate idea of the amount of ether being used at any moment can be obtained by looking at the sight-feed.

The ether driven by the current of air is vaporized in the warm coil and as it passes over the surface of the water it becomes saturated with moisture. Only a minimal amount of ether is absorbed by the water during the anesthesia, when the ether supply to the coil is discontinued, therefore, the flow of ether vapor into the tracheal tube promptly ceases. *It is to be emphasized* that the purpose of using warm water about the coil is solely to vaporize the ether. No attempt is made to warm the vapor, as the futility of such endeavors has been clearly demonstrated.

Furthermore, the passage of the vapor-laden air through the wide chamber above the water completely prevents the possibility of driving liquid ether into the tracheal tube.

A safety-valve is essential to an apparatus for intratracheal insufflation as emphasized by Melzer, and a manometer is also desirable in such an apparatus. Both have been provided in the machine here described, and for the sake of simplicity the two have been combined.

A glass tube is bent to form an elongated letter *S*. It is then so placed that one end opens into the air-space of the tank (*E*), and the other end is molded to form a cup which is covered with cotton and a perforated metal cap. The calibration arbitrarily chosen is that the distance (*X*) from the base of the cup to the concavity of the first curve shall be 2 cm. Into the manometer (*K*), mounted as shown in Figure 1, mercury is poured until (*Z*) the level of it in the arm (*Y*) is at the level of the base of the cup.



Apparatus for intratracheal insufflation: A, an electric motor, 0.1 h.p.; B, a piston pump with valves at C and D; C', a "spring-valve" to regulate the pressure of the stream of air; E; a metal tank nearly filled with warm water to vaporize the ether and to more completely saturate the air with moisture. F and F' are inlets for the current of air, nitrous oxid and oxygen. They are connected with a copper coil placed in E, and the outlet of this coil is at the surface of the warm water near F. G is the container for ether with a sight-feed at H and a narrow tube (I) to equalize the pressure at the upper level of the ether with that of the air-current. J is the tube through which the anesthetic enters the trachea. K is a combined mercury manometer and safety-valve.

With the restoration of the initial pressure the mercury will flow from the cup into the tube and the manometer will be reestablished. When there is change of pressure in the tank, it will cause a rise or a fall of the mercury in the tube (*Y*). The fluctuations of the level of mercury thus serve as an indicator of the pressure of the current of air blown into the trachea, and grossly indicate the character of the respiration. If for any reason the pressure becomes greater than 2 cm. Hg, the mercury from the tube will be forced into the cup and the air will escape until the excess of pressure is relieved. The tube is not graduated, for apparently it is not necessary to measure accurately the machine pressure. Eisenbrey[1] has shown that with a machine pressure of 50 mm. Hg the pressure in the trachea may be as low as 2.2 mm. Hg. The intratracheal pressure depends largely on the relative size of the tube to the trachea.

The safety-valve as described is satisfactory when the apparatus is used in anesthetizing patients in whom the chest wall is intact. When, however, the thorax is opened, no dependence is to be placed on records of machine pressure. The guide must be the condition of the exposed lung.

For an intratracheal tube a woven linen or silk catheter is used. This tube is introduced into the trachea through a Jackson pharyngoscope by direct inspection of the larynx. The procedure of introducing the tube is very simple.

---

[1] Eisenbrey: Surg., Gynec. and Obst., xv, 715.

If the apparatus had been made sensitive, that is, if the nitrous oxid effects could have been had in concentrated form for only two breaths, the anesthetic state would have come on quickly. On the other hand, if oxygen could have been supplied at the first symptom of jactitation the anesthesia would have been far different.

The solution of the difficulty is so simple that its application can be made to any apparatus. The nitrous oxid and the oxygen should be admitted near the face-piece, proximal to the mixing-chamber. The gases when thus admitted flow back into the bag or are respired directly as desired.

If the gas is admitted during an inspiration, the patient receives it in concentrated form; if during expiration, the gas admitted is carried along with the expired air into the rebreathing chamber. When the gas is shut off the rebreathing continues as usual.

The effects of concentrated oxygen may be obtained by simply allowing it to run slowly and continuously into the apparatus.

To my knowledge, concentrated oxygen never did harm.

Concentrated nitrous oxid is required only in a light anesthetic state; that is, when the nitrous oxid content in the circulation is low. This state of light anesthesia is not likely to be confounded with any other condition, for there is no general depression as in ether. There is usually active light reflex, lid reflex, muscular rigidity and some movement, depending on the shallowness of the anesthesia.

In addition to this, it requires several respirations to saturate the alveolar capillaries with nitrous oxid, even when absolutely pure gas is used. But in my case the contents of the rebreathing bag tend to dilute the nitrous oxid admitted, thereby giving a high percentage of nitrous oxid rather than an absolutely pure nitrous oxid. The rate of diffusion of gases depends on their relative densities; the greater the difference in densities the greater the rapidity of diffusion. Consequently the warm gas in the bag and the cold gas just admitted diffuse rapidly.

Furthermore, there appears to be no clinical evidence that nitrous oxid thus administered is in any way injurious.

The apparatus used by me at the Woman's Hospital illustrates this feature.

This apparatus is a modification of the S. S. White inhaler. This inhaler is machine made, with interchangeable parts. A transparent celluloid face-piece enables one to watch the patient closely. The apparatus is always taken down after each operation and can be thoroughly cleansed and sterilized. Only one valve is used, a simple disk made of mica. The weight of the apparatus is two-thirds of Bennet's apparatus. It can also be used for a simple gas-ether anesthesia or for gas-oxygen induction followed by gas-ether.

The use of standard parts requiring small modification makes it possible to put out this device complete, including the rubber goods, bag and tubing, for the sum of twenty-five dollars.

The principle emphasized by Dr. R. C. Coburn in the location of the bag and also the position of the ether-cup have been employed, and acknowledgment is here made for many valuable suggestions gathered from the writings and remarks of Dr. Coburn.

New Instruments and Suggestions

DESCRIPTION OF AN APPARATUS FOR INTRATRACHEAL INSUFFLATION

J. P. Pratt, M.D., Baltimore

Intratracheal insufflation as a method of anesthesia is now well established. It has already been the means of saving lives as well as increasing the possibilities of surgery. It is unnecessary to deal here with the advantages and disadvantages of this method, as they have been discussed sufficiently in recent medical literature An anesthetist to do the best work must be able to devote most of his time and attention to the patient, and his efficiency is decreased in proportion to the attention demanded by the apparatus used.

The apparatus here described is simple in construction and easy to manipulate.

The type of motor and pump used is almost noiseless. When the apparatus is in use it is well to have a foot bellows near by in the event that the motor should fail to work properly. The three inlet tubes (F, F' and the one to the right of F') are therefore arranged so that the connection with the pump may be retained intact while the bellows is being connected. Instead of a bellows a tank of nitrous oxid or of oxygen may be employed.

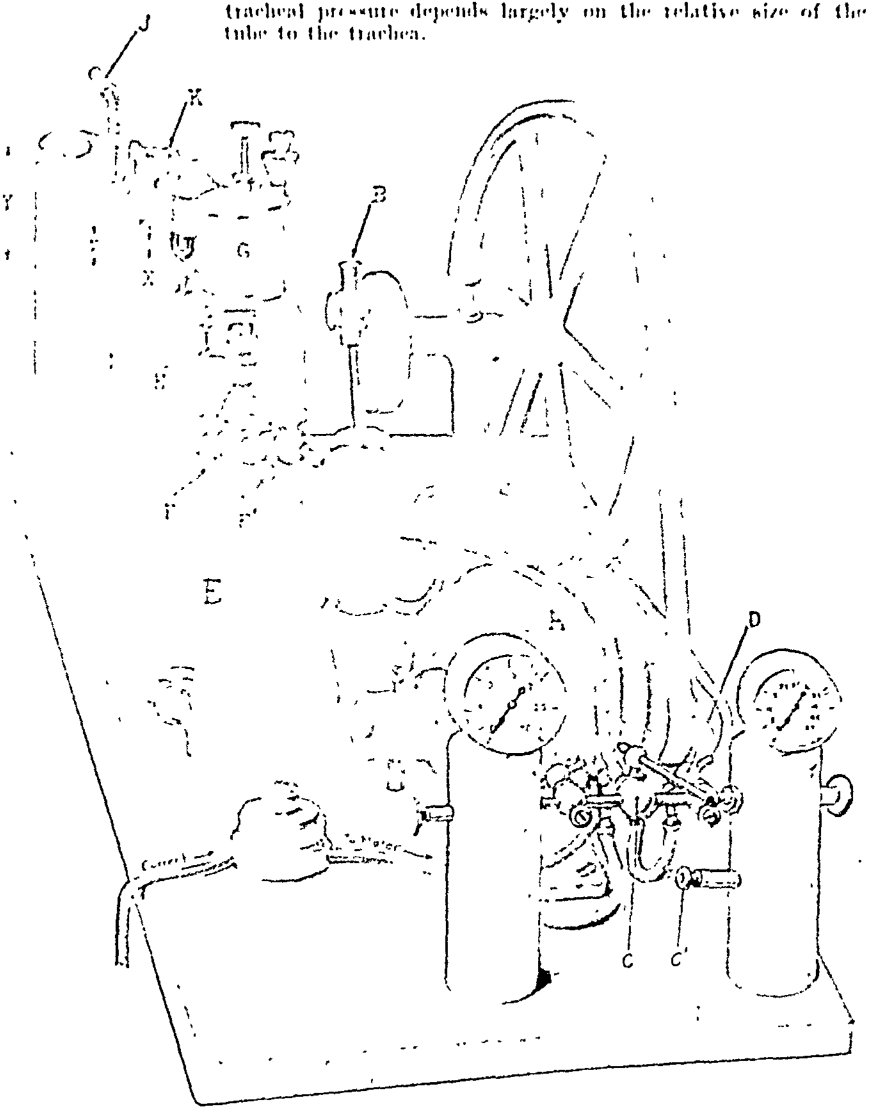
The ether container, as already noted, is provided with a pressure equalizer. Were it not for this equalizer, the ether would be driven back into the container when pressure is admitted from below. The installation of the equalizing tube allows the ether to drop at the constant rate desired. This method of introducing the ether into the air-current has the following advantages: (1) any concentration of ether desired can be obtained; (2) the concentration is readily controlled; (3) an accurate idea of the amount of ether being used at any moment can be obtained by looking at the sight-feed.

The ether driven by the current of air is vaporized in the warm coil and as it passes over the surface of the water it becomes saturated with moisture. Only a minimal amount of ether is absorbed by the water during the anesthesia, when the ether supply to the coil is discontinued, therefore, the flow of ether vapor into the tracheal tube promptly ceases. It is to be emphasized that the purpose of using warm water about the coil is solely to vaporize the ether. No attempt is made to warm the vapor, as the futility of such endeavors has been clearly demonstrated. *Furthermore, the passage of the* vapor-laden air through the wide chamber above the water completely prevents the possibility of driving liquid ether into the tracheal tube.

A safety-valve is essential to an apparatus for intratracheal insufflation as emphasized by Melzer, and a manometer is also desirable in such an apparatus Both have been provided in the machine here described, and for the sake of simplicity the two have been combined.

A glass tube is bent to form an elongated letter *S*. It is then so placed that one end opens into the air-space of the tank (*E*), and the other end is molded to form a cup which is covered with cotton and a perforated metal cap. The calibration arbitrarily chosen is that the distance (*X*) from the base of the cup to the concavity of the first curve shall be 2 cm. Into the manometer (*K*), mounted as shown in Figure 1, mercury is poured until (*Z*) the level of it in the arm (*Y*) is at the level of the base of the cup.

With the restoration of the initial pressure the mercury will flow from the cup into the tube and the manometer will be reestablished. When there is change of pressure in the tank, it will cause a rise or a fall of the mercury in the tube (*Y*). The fluctuations of the level of mercury thus serve as an indicator of the pressure of the current of air blown into the trachea, and grossly indicate the character of the respiration. If for any reason the pressure becomes greater than 2 cm. Hg. the mercury from the tube will be forced into the cup and the air will escape until the excess of pressure is relieved. The tube is not graduated, for apparently it is not necessary to measure accurately the machine pressure. Eisenbrey[1] has shown that with a machine pressure of 50 mm. Hg the pressure in the trachea may be as low as 2.2 mm. Hg. The intratracheal pressure depends largely on the relative size of the tube to the trachea.



Apparatus for intratracheal insufflation: A, an electric motor, 0.1 h.p.; B, a piston pump with valves at C and D; C', a "spring-valve" to regulate the pressure of the stream of air; E; a metal tank nearly filled with warm water to vaporize the ether and to more completely saturate the air with moisture. F and F' are inlets for the current of air, nitrous oxid and oxygen. They are connected with a copper coil placed in E, and the outlet of this coil is at the surface of the warm water near F. G is the container for ether with a sight-feed at H and a narrow tube (I) to equalize the pressure at the upper level of the ether with that of the air-current. J is the tube through which the anesthetic enters the trachea K is a combined mercury manometer and safety-valve.

The safety-valve as described is satisfactory when the apparatus is used in anesthetizing patients in whom the chest wall is intact. When, however, the thorax is opened, no dependence is to be placed on records of machine pressure. The guide must be the condition of the exposed lung.

For an intratracheal tube a woven linen or silk catheter is used. This tube is introduced into the trachea through a Jackson pharyngoscope by direct inspection of the larynx. The procedure of introducing the tube is very simple.

---

[1] Eisenbrey: Surg., Gynec. and Obst., xv, 715.

After the patient is well anesthetized with ether and while he is in the dorsal position, the pharyngoscope is inserted. The head is not allowed to hang over the end of the table, nor is it hyperextended, as advocated by some surgeons. Either one of these maneuvers is not only unnecessary, but really complicates the procedure, especially should it be necessary to introduce the tube during an operation. Such an emergency arose in the Johns Hopkins Hospital recently. The patient had an aneurysm of the thoracic aorta which caused a partial occlusion of the trachea. The operation was the application of an aluminum band for a femoral aneurysm. The patient had had attacks of dyspnea previous to the operation, so the anesthesia was undertaken with some anxiety. A tube was not introduced into the trachea at first for fear of rupturing the thoracic aneurysm. Considerable difficulty was experienced throughout the anesthesia in obtaining a free exchange of air. Finally, the patient became cyanotic, no air passing in or out of the lungs, although the respiratory movements were violent. The air-passages were quite free as far as the larynx, so it was evident that the obstruction was below that structure. A tube was inserted into the trachea. As it reached the level of the thoracic aneurysm a large piece of thick mucus was forcibly expelled, the obstruction was immediately relieved, and the patient's breathing became tranquil. This case illustrates two things: first, the necessity, in certain cases, of having a means of relieving tracheal obstruction; second, the possibility of introducing a tube without disturbing the position of the patient or the field of operation.

Johns Hopkins Hospital.

A BURET FOR INTRASPINOUS MEDICATION

W. F. Lorenz, M.D., Mendota, Wis.

Adopting the Greiner and Friedrich three-way stop-cock, I designed a buret for intraspinous medication. The instrument has been employed in a large number of cases. It has been found very satisfactory in treating tabes by the Swift-Ellis method and in the direct administration of neosalvarsan into the spinal canal.

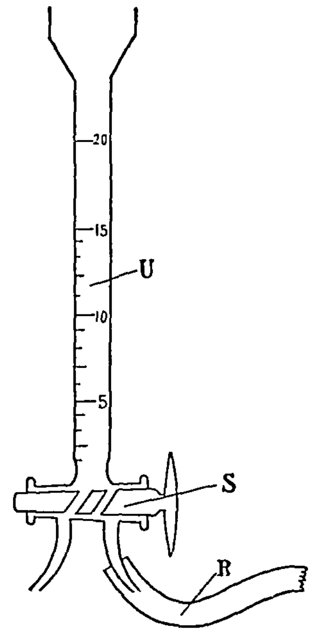


Fig. 1.—Buret for intraspinous medication.

In Figure 1, in which an effort is made to show the principle on which the buret operates, *U* indicates the upright or vertical arm. It is 28 cm. in length, 1 cm. in diameter and graduated in cubic centimeters up to 20. *S* indicates the three-way stop-cock; *R* indicates the rubber tubing which connects the instrument with the puncturing needle.

The buret is employed in the following manner: As soon as the canal is entered and fluid is obtained, the rubber tubing marked *R* is attached to the needle. The spinal fluid soon appears and gradually (the speed is entirely at the operator's choice) accumulates in the upright. This outflow can be stopped at any point by a quarter-turn at *S*. By a half-turn at *S*, the fluid in the upright is discharged at the unattached spout, where the fluid can be collected for subsequent examination. The serum or solution which is to be administered can now be poured into the upright. By turning the stop-cock *S*, the upright is again made continuous with the puncturiing needle and the return flow begins. The speed of this return can be affected by raising or lowering the instrument. The flexible rubber tubing *R* permits this change of height and consequently the speed of the returning fluid is at the disposal of the operator. When the returning fluid has reached the spout, the stop-cock is turned and all further movement of the fluid ceases.

I have used a rubber tubing 10 cm. in length of about 3 mm. caliber, containing by measurement 1 c.c. of fluid. In a number of instances a rubber tube 6 cm. in length was found perfectly satisfactory. The longer tube, however, permits greater altitude, which occasionally is necessary.

The advantages of this method are: 1. The glass instrument can be readily sterilized. 2. The fluid drawn is visible. 3. The rate of flow either way can be controlled. 4. The pressure can be quite accurately estimated according to the height to which the fluid is forced. 5. No handling of spinal fluid that returns into the canal is necessary. 6. The serum or solution to be introduced can be thoroughly mixed with the spinal fluid remaining in the upright arm previous to its return flow.

Figure 2 represents the attachment to the needle employed by myself during a lumbar puncture or intraspinous treatment. *M* indicates a metal stop-cock with a vertical outlet, to which is attached a capillary tube by means of a small piece of rubber tubing, the latter sufficiently firm to hold the capillary tube upright without support. The metal stop-cock has a universal thread at one outlet to which is attached the puncturing needle. The other outlet is for rubber tube connections when the previously described buret is employed.

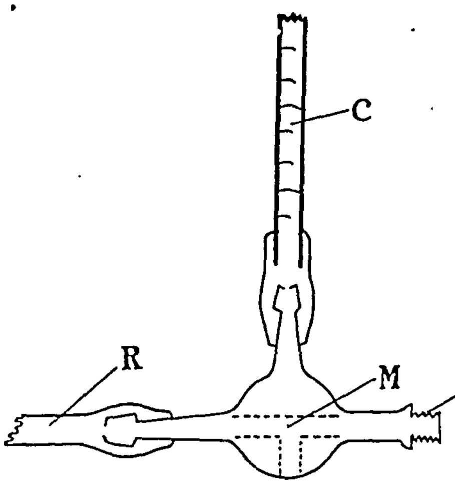

Fig. 2.—Attachment to the needle employed during a lumbar puncture or intraspinous injection.

At the time of puncture the metal stop-cock is attached to the needle. As soon as the canal is reached and fluid appears at the *R* outlet, the capillary tube is attached to the vertical arm and stop-cock *M* is given a quarter-turn; the spinal fluid then appears in the capillary tube and its height is noted. If an intraspinous treatment is to be given, the rubber tube connection *R* is made with the buret and the procedure described above is followed. After the administration, or after a simple withdrawal of spinal fluid, the reduction in pressure can be observed by simply turning stop-cock *M* until the capillary tube is again continuous with the canal.

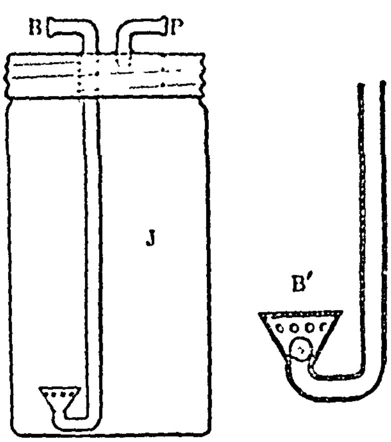
SAFEGUARDING THE ETHER AND CHLOROFORM BOTTLES

Tracy L. Fisk, M.D., New York

Anesthetist, Bronx Eye and Ear Infirmary and Union Hospital

The vapor method or insufflation method of anesthesia is gaining ground so rapidly, especially in the hospitals, that I feel called on to point out a grave and entirely needless danger connected with the use of the apparatus as now manufactured or improvised. In this city Dr. Gwathmey's three bottles constitute the most popular form of container for the anesthetic. One bottle is for chloroform, one for ether and the third is a wash, overflow and warming bottle, which contains water. A more elaborate apparatus devised by Dr. Lumbard is also used. This has four bottles, two being for ether, one for chloroform, and one for water. Since chloroform has fallen into comparative disuse, many anesthetists use a single ether bottle which they improvise by inserting a long and a short glass tube in the rubber stopper of any wide-mouthed bottle of suitable capacity.

All the before-mentioned apparatus, whether manufactured by the instrument-makers or put together by the anesthetist, has the same serious fault, namely, that if it be connected wrongly, the air-pump or bellows will drive liquid ether or chloroform down the patient's throat, up his nose or into his trachea, according to whether a hollow mouth gag, nasal tubes or an intratracheal tube be used to administer the anesthetic. This deplorable accident has resulted fatally in several cases.[1] Hence Meltzer, in describing his intratracheal insufflation apparatus, says that the ether bottle should be equipped with two short tubes only, instead of one long and one short tube. Thus there would be no tube below the surface of the ether. In Meltzer's method of intratracheal etherization such an arrangement is admirable, but in ordinary anesthesia by the vapor method (as for example in adenoid and tonsil operations in which the tubular mouth gag is used) I have found it impossible to obtain an effective concentration of ether vapor in this way. Short tubes terminating above the level of the ether will not bring about satisfactory anesthesia, except in very susceptible cases. We may be sure then that anesthetists in general will continue to use the long tube in the ether bottle. Operating room nurses, whatever their ability, are not bachelors of science or even master mechanics. It is therefore not surprising that sometimes in the hurry of preparing for an operation they connect the short glass tube to the bellows and connect the long glass tube to the mask or mouth-gag. When the intern, perhaps too tired from twenty-four-hour duty to be alert, begins to work the foot-bellows the result may be disastrous, particularly in those cases in which the patient has been anesthetized by othe methodr before the insufflation is begun.



J, ether bottle, complete; *B′*, cross section of lower end of pipe *B*, showing ball-valve.

To render such accidents impossible I have made an ether bottle or jar as follows (the materials cost only a few cents at any large hardware store):

B and *P* are two soft brass or copper tubes, each 3/16 inch in outside diameter, which pass through and are soldered to the tin or brass screw-top of the pint jar *J*, which top rests on a cork disk or washer not shown. *B*, which, when in use should be connected to the bellows, is long enough to reach nearly to the bottom of the jar, at which point it is turned upward. The end is filed or ground flat and the inside of the tube is bored out a little with a drill to make it perfectly round. The end of this tube forms the valve-seat. This is tested by holding a 3/16 bronze ball against it and attempting to blow or suck air through the pipe. If not air-tight the seat should be ground by rotating a steel ball 3/16 inch in diameter against the end of the tube, with fingers or pliers, using some fine emery and oil until perfect fit is obtained.

A conical brass cuff about ¾ inch high and ⅝ inch in diameter is now soldered to the end of pipe *B*, the large end of the cone being upward, as shown. The small end of the cone is of course just large enough to fit snugly outside of pipe *B*. The sides of the cone are perforated with about eight holes each 1/16 in diameter. The bronze ball, which has not been used for grinding purposes, is now dropped into the cone and rests snugly on the valve seat. This is tested again, and if air-tight a lid is put over it, namely, a flat disk ⅝ inch in diameter with four spurs each ¼ inch long projecting from its circumference, which, when bent down on the cone, serve as clamps. For the lid and cone 1/32 inch soft sheet brass is used, as it is easily cut with tinner's snips.

The pipe *P*, which will carry the vapor toward the patient, terminates just below the top of the jar. At this point it is completely surrounded by a brass wire gauze cage of fine mesh. This is cylindrical, about 1 inch in diameter and ¾ inch long. It prevents the ether from splashing into pipe *P* during rapid pumping. It may be said that this wire cage is unnecessary when a water-bottle is used. Many anesthetists, however, use no water-bottle. I therefore prefer to have the apparatus complete in itself so far as possible, though a water-bottle is an additional protection. When no water-bottle is used, the ether bottle should not be filled more than three-fifths full. Otherwise violent pumping might throw a little spray of ether into pipe *P*, in spite of the cage. When a water-bottle is used it is of course attached by rubber tubing to pipe *P*, and from the water-bottle another rubber tube goes to the mask. (When by mistake pipe *B* is connected to the mask and pipe *P* is connected to the bellows, the ball valve, if properly made, will prevent any ether from going to the patient, though the anesthetist should pump until the bellows burst.) A few layers of surgical gauze placed in the ether jar about the lower end of pipe *B* will greatly increase the strength of the vapor by finely dividing the air. This point is of service in anesthetizing refractory subjects.

I have described this simple apparatus in detail in the hope that many anesthetists and house surgeons who are skilful with file and soldering-iron will make their own safety ether bottles, and that instrument-makers will safeguard all the bottles which they turn out. Thus we shall stop these disgraceful accidents, few of which in all probability are reported.

1981 Southern Boulevard.

AN IMPROVED DIPHTHERIA CULTURE-TUBE *

C. C. Bass, M.D., New Orleans

Those who have occasion to take throat cultures for the diagnosis of diphtheria will no doubt appreciate some of the advantages of the tube shown in the accompanying illustration, and proposed by me to take the place of the usual outfit supplied by board of health laboratories and others for this purpose.

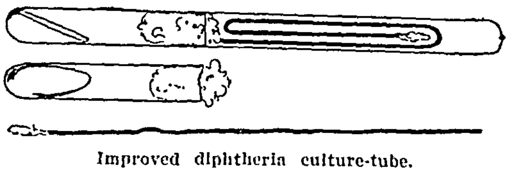
Tubes 1 cm. in diameter (outside measure) and 12 cm. long are the proper size for this purpose. The swab should be made of No 18 copper wire, 12 cm. long, and bent so that it can be placed in the tube above the cotton plug, as illustrated. Five-tenths c.c. of the Loeffler serum mixture is the proper amount to make a slanted surface about 2 cm. long in tubes of this size.

After the serum mixture, cotton plug and swab are placed in the tubes as indicated, they are hermetically sealed. This can be done rapidly with the aid of a blow-pipe or blow-torch. They are now sterilized in the proper slanting position. Finally, they are marked with a file or glass cutter near the junction of the middle and upper thirds of the length of the plug. When broken for use, one end of the tube is a small culture tube and the other end contains the swab, which can be straightened out for use.

Some of the advantages of this tube are:

1. It keeps indefinitely, and does not dry out or become infected.

2. It is small and does not occupy so much space as the usual package in one's satchel or pocket. The surface of culture material, however, is greater than is put to practical use in making ordinary throat-cultures.



Improved diphtheria culture-tube.

3. The tubes can be made up at less cost than the usual package. The fact that the medium does not deteriorate is a further source of economy.

Those likely to have occasion to take throat-cultures will find it to their advantage to add one or more of these tubes to their armamentarium in order to avoid the delay and dissatisfaction often occasioned in obtaining tubes from a drug-store or laboratory. Board of health laboratories should adopt and supply this form of tube. They could be placed on the market by manufacturers to be sold profitably for a few cents apiece.

741 Carondelet Street.

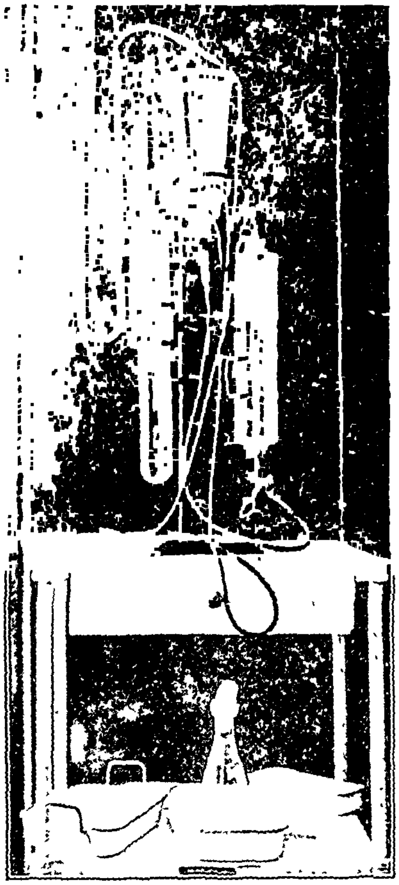
APPARATUS FOR ARTIFICIAL PNEUMOTHORAX

Lewis Sayre Mace, M.D., San Francisco

During the past year I have had occasion to make and use several kinds of apparatus for artificial pneumothorax. The accompanying illustration shows the form and arrangement which I have found most practical and simple, while fulfilling all the requirements for this operation.



Apparatus for artificial pneumothorax.

The apparatus described by Forlanini consists essentially of a water and mercury manometer and graduated cylinders to hold the gas and displacing fluid mounted on a wooden stand. The Forlanini apparatus is difficult to obtain, expensive, and too cumbersome to be easily transported.

Many different forms of apparatus have been made by operators in this country, but the one I am describing seems to me to be the one most free from disadvantages.

This consists of a buret stand, to which is attached a water manometer, cylinder for gas and percolator above for displacing liquid. In addition to these are the wash-bottle and continuous pressure manometer, as described by me in The Journal, Nov. 1, 1913, p. 1629.

These articles—buret stand, clamps and glassware—can always be found in stock in supply-houses and require but a few minutes to assemble.

The whole apparatus can be packed in a small grip and carried to the bedside.

The glass cylinders for containing the gas presented the greatest difficulty until I found that the cylinders of the ordinary glass rolling pin were of the right size and most conveniently made with a hole at each end. These contain about 1 liter each and any number of them can be filled and carried to an operation. They are fitted with one-holed rubber stoppers at each end, and when in use the gas is displaced from below as shown in the illustration.

240 Stockton Street.

AN IMPROVED EAR-SPECULUM

Ralph Waldo Place, M.D., Somerville, Mass.

This ear-speculum gives a larger field than those in common use and therefore greater freedom to the operator. By using the ordinary ear-spoon with it, a foreign body or hardened mass of cerumen can be grasped and withdrawn. In this way it is used as a scoop.

Improved ear-speculum.

Those who do much ear work will appreciate the fact that it is easy to clean.

The Frank S. Betz Company have made me several models in aluminum, and the instrument may be obtained from them in three sizes.

165 Medford Street.

A SIMPLE INSTRUMENT FOR TRANSFUSION*

Bernard Francis McGrath, M.D., Rochester, Minn.

Although blood transmitted through tubes or aspirated and injected has been proved to be practically effective, yet is not that method which causes the nearest *approximation to* the normal vascular condition the logical one? Because of the *nature of the work, desiderata in any method of transfusion* are simplicity and rapidity in its execution; and an essential is sureness of flow. The instrument and method of application shown in Figures 1, 2 and 3 I have found practical in experimentation. The intima of the donor is applied to the intima of the recipient in a direct line, with no foreign substance at the point of union, and only the slightest locking of the forceps is necessary to prevent leakage.

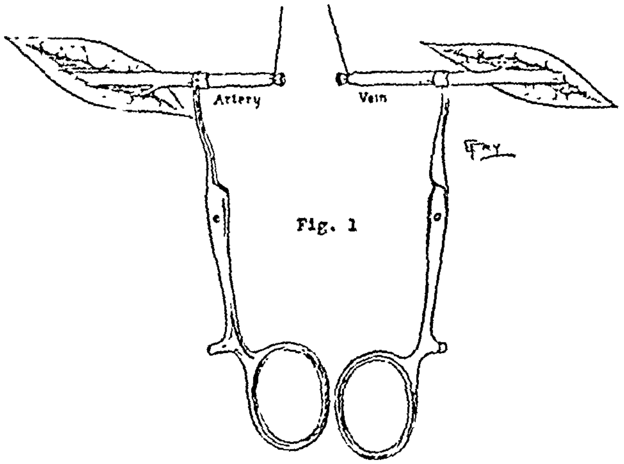


Fig. 1.—Vessels drawn through cannula by means of ends of ligatures.

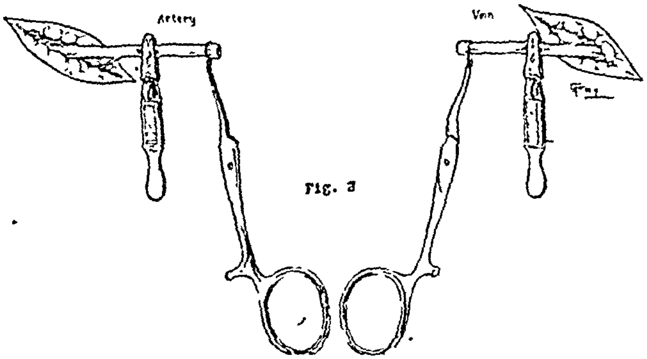

Fig. 2.—Vessels cuffed on cannula and fixed on sharp hooks.

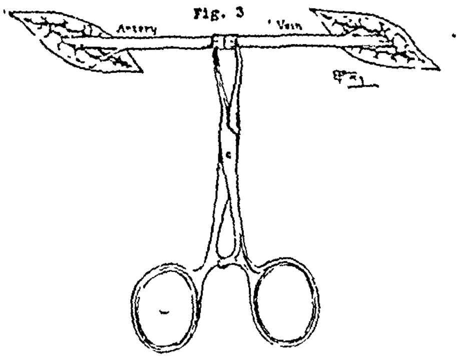

Fig. 3.—Forceps lightly clamped after allowing blood to flow from cannula.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

RADIUM AND RADIUM SALTS

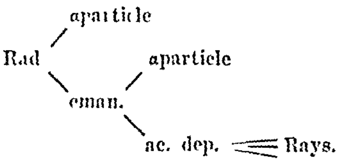
Radium is a bivalent metallic element closely related to barium. It is exceedingly reactive, making it difficult to isolate in its metallic state and after isolation to keep in a pure state, as it reacts with air, forming the oxide, nitrite and finally the carbonate. On account of this activity it is only produced in the form of its salts, principally as the bromide, chloride, sulphate and carbonate.

The most important property of radium is its radio-activity upon which depends its therapeutic value. Radio-activity is defined as "the property of spontaneously emitting radiations capable of passing through plates of metal and other substances opaque to ordinary light and having the power of discharging electrified bodies." A spontaneous disintegration of the atoms characterizes all the radio-active elements and it is in this transmutation or splitting of the atom that the rays are shot out, some being material in nature, others electrical or of the nature of light. This spontaneous transmutation of radium is going on at a regular rate, which is independent of the state of combination of radium in the molecule of its compounds.

To determine the radio-active value of radium, use is made of its property of ionizing gases. Thus when radium is allowed to act on the air in a charged gold leaf electroscope the air becomes ionized and therefore a conductor of electricity and allows the charge to leak out, causing the leaf in the electroscope to move. By observing the rate of movement of the leaf in a calibrated apparatus the radio-activity can be determined.

Quantities and concentrations of radium emanation are expressed in terms of "curies" and Mache units. A "curie" is the amount of emanation in equilibrium with 1 gram of radium; a microcurie, one millionth of a "curie," is the amount of emanation in equilibrium with 0.001 mg. radium and is equivalent to about 2,500 Mache units.

Relation of Radium, Radium Emanation and Rays.—The rays are largely derived indirectly from radium through the formation of its "active deposit," according to the following scheme:



These rays are divided into three groups, the alpha, beta and gamma, which differ in their velocity and penetrative power. The alpha and beta rays consist of minute particles of matter electrically charged and moving with a velocity almost equal to that of light. They are for the most part of relatively feeble penetrating power. The gamma rays are vibrations in the ether, very similar to x-rays, and of high penetrating power. Therapeutically the last group is the most useful.

Radium emanation is continuously given off from aqueous solutions of radium salts. It can be collected as it escapes from the solution, drawn off through the use of the mercury pump, or by other suitable means, quantitatively determined by either the alpha or gamma ray electroscope, brought into solution in water for internal or external use or be set free in an emanatorium for inhalation treatment. It may be collected into small glass containers and this used in place of the applicators described under surgical use.

Actions and Uses: Radium emanation is said to increase the excretion of uric acid in the urine and to decrease its concentration in the blood; to increase somewhat the number of red blood-corpuscles; to cause temporary leukocytosis early in the course of treatment, the mononuclear increase being relatively greater; to lead frequently through long-continued use to leukopenia, although no appreciable benefit is observed in leukemia. It is said that radium increases general metabolism, and *in vitro* activates certain enzymes, pepsin, pancreatin, rennin, autolytic ferments, tyrosinase and diastase.

It has been claimed that radium emanation is of value in all forms of non-suppurative, acute, subacute and chronic arthritis (luetic and tuberculous excepted), in chronic muscle and joint rheumatism (so-called), in arthritis deformans, in acute and chronic gout, in neuralgia, sciatica, lumbago, and in tabes dorsalis for the relief of lancinating pains. Its chief value is in the relief of pain.

Surgical Use: The efficiency of the treatment is due to the beta and gamma rays. The quantity of ray is proportional to the amount of radium element represented in the salt or the emanation. Pure gamma rays may be employed when the apparatus is surrounded by at least 3 mm. of lead. Nearly all pathologic tissues are more sensitive than normal tissues. There is, however, a wide variation in the normal tissues: e. g., the ovary and the sexual organs are very sensitive, the eye and nervous tissues very unsensitive. In skin diseases marked results are obtained with epitheliomata, birthmarks and scars.

Technic. Usually heavy doses with epitheliomata, light doses with other conditions. New growths, benign and malignant, of the pelvic organs, the breast, the neck and other parts of the body have been most favorably influenced in some cases. The growths of the mucous membrane of the mouth are quite resistant. There is a remarkable sedative effect in true neuralgias, as well as those due to tumor pressure. The dosage for internal work is heavy, "hundreds of milligrams," and always with the pure gamma rays. The technic of filtration, of length of application and of amount is still in an experimental stage.

The radium salts and the emanation can be placed in any sealed container, but preferably in glass.

Dosage. It may be administered as baths, by subcutaneous injection in the neighborhood of an involved joint (0.25 to 0.5 microcurie in 1 or 2 Cc. distilled water), by local application as compresses (5-10 microcuries), by mouth as a drink cure (in increasing doses of from 1-10 to 10 microcuries three or more times a day), by inhalation, the patient for two hours daily remaining in the emanatorium, which contains 0.0025 to 0.25 (average 0.1) microcurie per liter of air.

RADIUM CHLORIDE.—Radium chloride is the anhydrous radium salt, $RaCl_2$, of hydrochloric acid. While nearly pure radium chloride, containing 76.1 per cent. radium (Ra), is said to be obtainable, the market supply is a mixture of radium chloride and barium chloride and is sold on the basis of its radium content.

Actions and Uses: See Radium.

Dosage. See Radium.

Non-Proprietary Preparation:

Radium Chloride, Standard Chemical Co.—Radium chloride is supplied in the form of a mixture of radium chloride and barium chloride for use in radium baths, radium drinking-water and inhalatoriums. It is sold on the basis of its radium content.

Manufactured by the Standard Chemical Co., Pittsburgh, Pa. (The Radium Chemical Co., Pittsburgh, Pa.).

Pure anhydrous radium chloride occurs as a white or slightly brownish crystalline substance, soluble in water.

The presence of radium can qualitatively be demonstrated by electroscopic or by photographic methods.

The quantitative determination of radium is carried out according to the method of Rutherford and Boltwood (Rutherford's "Radioactive Substances and their Radiations").

RADIUM SULPHATE.—Radium sulphate is the anhydrous radium salt, $RaSO_4$, of sulphuric acid. While nearly pure radium sulphate, containing 70.2 per cent. (Ra), is said to be obtainable, the market supply is a mixture of radium sulphate and barium sulphate and is sold on the basis of its radium content.

Actions and Uses. See Radium.

Dosage. See Radium.

Non-Proprietary Preparation:

Radium Sulphate, Standard Chemical Co.—Radium sulphate supplied in the form of a mixture of radium sulphate and barium sulphate for use in applicators. It is sold on the basis of its radium content.

[illegible] nical Co., Pittsburgh, Pa.
[illegible] Pa.)

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

RADIUM AND RADIUM SALTS

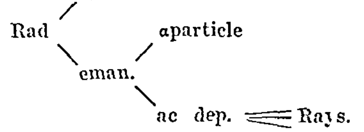
Radium is a bivalent metallic element closely related to barium. It is exceedingly reactive, making it difficult to isolate in its metallic state and after isolation to keep in a pure state, as it reacts with air, forming the oxide, nitrite and finally the carbonate On account of this activity it is only produced in the form of its salts, principally as the bromide, chloride, sulphate and carbonate

The most important property of radium is its radio-activity upon which depends its therapeutic value. Radio activity is defined as "the property of spontaneously emitting radiations capable of passing through plates of metal and other substances opaque to ordinary light and having the power of discharging electrified bodies." A spontaneous disintegration of the atoms characterizes all the radio active elements and it is in this transmutation or splitting of the atom that the rays are shot out, some being material in nature, others electrical or of the nature of light This spontaneous transmutation of radium is going on at a regular rate, which is independent of the state of combination of radium in the molecule of its compounds.

To determine the radio active value of radium, use is made of its property of ionizing gases. Thus when radium is allowed to act on the air in a charged gold-leaf electroscope the air becomes ionized and therefore a conductor of electricity and allows the charge to leak out, causing the leaf in the electroscope to move. By observing the rate of movement of the leaf in a calibrated apparatus the radio activity can be determined

Quantities and concentrations of radium emanation are expressed in terms of "curies" and Mache units. A "curie" is the amount of emanation in equilibrium with 1 gram of radium; a microcurie, one millionth of a "curie," is the amount of emanation in equilibrium with 0.001 mg radium and is equivalent to about 2,500 Mache units

Relation of Radium, Radium Emanation and Rays.—The rays are largely derived indirectly from radium through the formation of its "active deposit," according to the following scheme:



These rays are divided into three groups, the alpha, beta and gamma, which differ in their velocity and penetrative power. The alpha and beta rays consist of minute particles of matter electrically charged and moving with a velocity almost equal to that of light. They are for the most part of relatively feeble penetrating power. The gamma rays are vibrations in the ether, very similar to x-rays, and of high penetrating power. Therapeutically the last group is the most useful.

Radium emanation is continuously given off from aqueous solutions of radium salts It can be collected as it escapes from the solution, drawn off through the use of the mercury pump, or by other suitable means, quantitatively determined by either the alpha or gamma ray electroscope, brought into solution in water for internal or external use or be set free in an emanatorium for inhalation treatment. It may be collected into small glass containers and this used in place of the applicators described under surgical use

Actions and Uses: Radium emanation is said to increase the excretion of uric acid in the urine and to decrease its concentration in the blood; to increase somewhat the number of red blood-corpuscles; to cause temporary leukocytosis early in the course of treatment, the mononuclear increase being relatively greater; to lead frequently through long-continued use to leukopenia, although no appreciable benefit is observed in leukemia. It is said that radium increases general metabolism, and *in vitro* activates certain enzymes, pepsin, pancreatin, rennin, autolytic ferments, tyrosinase and diastase

It has been claimed that radium emanation is of value in all forms of non-suppurative, acute, subacute and chronic arthritis (luetic and tuberculous excepted), in chronic muscle and joint rheumatism (so-called), in arthritis deformans, in acute and chronic gout, in neuralgia, sciatica, lumbago, and in tabes dorsalis for the relief of lancinating pains. Its chief value is in the relief of pain.

Surgical Use: The efficiency of the treatment is due to the beta and gamma rays. The quantity of ray is proportional to the amount of radium element represented in the salt or the emanation. Pure gamma rays may be employed when the apparatus is surrounded by at least 3 mm. of lead. Nearly all pathologic tissues are more sensitive than normal tissues. There is, however, a wide variation in the normal tissues; e. g., the ovary and the sexual organs are very sensitive, the eye and nervous tissues very unsensitive. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street . . . Chicago, Ill.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

Contributors, subscribers and readers will find important information on the second advertising page following the reading-matter.

SATURDAY, JANUARY 3, 1914

Recently the bona-fide circulation of The Journal of the American Medical Association reached and passed the 60,000 mark. This does not include sample copies; it comprises only the actual circulation. Compared with that of lay weekly publications this would not be considered remarkable; but for a scientific or class publication, especially with such a limited clientele as the medical profession, this circulation must be regarded as very large. It is much more than double the combined paid circulation of all other weekly medical journals in this country, and is very nearly equal to the total paid circulation of all other medical weeklies published in the English language. At the present time approximately 39,000 subscribers are Fellows — until recently called "members" — of the American Medical Association. The remaining subscribers alone, over 20,000, equal the total number of paid subscribers to the four other medical weeklies in the United States. Heretofore the number given on the title-page of The Journal week by week has been much below the actual circulation. Beginning this week, the figures given will represent the actual number of copies printed, and will include sample copies and also those held as reserves.

THE LESSONS OF AN EXPERIMENT IN THE SUPPRESSION OF VENEREAL DISEASES

The propaganda for the suppression of venereal disease has probably departed further from the rules of practical experience, and hesitated more to adopt or advocate measures which have demonstrated their usefulness in allied directions, than has the agitation for the control of any other chronic infectious disorder of man. It is becoming increasingly more obvious that campaigns of public education, important and directive as they have been proved to be in all movements for the general welfare, cannot of themselves stamp out a disease that rivals tuberculosis as a cause of incapacity, sickness and misery. Now that the causes and mode of transmission of syphilis are known and modern discoveries have afforded such satisfactory aids to accurate diagnosis, it is time to give greater latitude to the recommendations of medical science; for it is becoming more and more evident that the problems can be solved only by the joint efforts of the publicist, the statesman and the physician. In an interesting account of the remarkable piece of work which has been done in the state of Victoria, Australia, and particularly at Melbourne, Dr. James W. Barrett[1] has indicated why medical men have encountered so much difficulty in combating some of the contagious diseases. The management of these diseases has always been complicated by the admixture of practical medicine with morality. Medical men dislike vice, Dr. Barrett rightly says, perhaps rather more than most persons, because they see so much of its nauseous side; but medical men as such are not teachers of morality; their primary duty is to prevent and cure disease.

A right understanding of the facts is a necessary foundation for public action. The first step was to obtain first-hand evidence of the actual distribution and incidence of venereal diseases. For twelve months syphilis was made a compulsorily notifiable disease in *an area of ten miles' radius from the general post-office* in Melbourne. This plan, admittedly imperfect, despite the fact that no names were given, and that Wassermann tests were conducted without charge and a fee was paid to any practitioner for reporting the cases and collecting blood, aroused an unexpectedly cordial response in the profession as a whole. At the end of the year, out of 5,000 cases reported and tested, 3,167 proved to be syphilitic. In another of these public experiments at the Victorian Eye and Ear Hospital, 13.3 per cent. out of 550 patients examined, irrespective of the disease or condition which had caused them to visit the institution, were syphilitic. Such data indicating the incidence of syphilis in a considerable fraction of a population, taken at random and systematically published in unexpurgated form, furnished convincing evidence to demonstrate the magnitude of the problem.

As the outcome of these findings it was decided by a conference of the various interested committees of the laity and the medical profession not to advocate any contagious disease act to remedy the situation, but to attack it in another manner. Wards were equipped by the government in at least two hospitals in Melbourne for the treatment of persons of any class, except prostitutes, who were suffering from venereal diseases in contagious forms. The object was not so much solicitude for the sufferers as a desire to prevent further infection. The profession was circularized and asked to send patients for treatment and advice. The Australian government has further arranged with the University of Melbourne for the free application of the Wassermann test to 2,000 hospital patients a year, and to all others at a very low fee. Lastly, it is proposed to introduce a modification of an act already in force in New South Wales to provide that any person sentenced to a term of imprisonment for any cause, if found to be suffering from contagious venereal disease, can be detained until his release is free from risk to other persons.

---

[1] Barrett, J. W.: The Suppression of Venereal Diseases: An Australian Experiment, Bedrock, 1913, ii, 102.

In contrast with many other hastily conceived plans of procedure, the entire conduct of this Australian movement strikes one as eminently intelligent, temperate and efficient. The attack along medical lines has followed a comprehensive investigation into the real occasion for such an undertaking. All the agencies for the removal of social excrescences and the gradual recasting of social relationships have cooperated under the dominant influence of medical leadership.

HEXAMETHYLENAMIN

The well-established fact that hexamethylenamin acts in some cases as an efficient urinary antiseptic led to its wide use for the prophylaxis of typhoid cystitis and other infections of the genito-urinary tract. The first publications of Nicolaier showed that this drug decomposes in acid urines with the formation of formaldehyd, which then exerts a marked antiseptic action. When Crowe and others showed that hexamethylenamin passes into all the tissues and body fluids, the hasty generalization was made that it would act as efficiently against infection in other organs as it did in the bladder. This deduction was apparently supported by clinical observations, although some unsuccessful cases made the results indecisive.

Laboratory experiments show that the activity of hexamethylenamin depends on its decomposition into formaldehyd and ammonia. This decomposition takes place only in an acid medium. How, then, can hexamethylenamin have an antiseptic action in the tissues, which are alkaline in reaction?

An attempt was made to solve this question by the application of tests for formaldehyd directly to the body fluids after the administration of hexamethylenamin. Unfortunately, some investigators employed tests that did not differentiate between hexamethylenamin and formaldehyd, so that their results were worthless. The paper of Burnham was especially serviceable in calling attention to this point. When tests were used which respond to formaldehyd alone, his results, and incidentally those of others who preceded and succeeded him, were negative except as to the urine. They showed that formaldehyd was not present in the other body fluids. The tests themselves, however, were not always convincing; and even if their correctness was granted, they were not absolutely decisive. It might be objected that the formaldehyd disappeared about as rapidly as it was formed. This objection was answered by the work of Smith and the later investigations of Hanzlik and Collins,[1] who proved that the liberation of formaldehyd can occur only in fluids having an acid reaction according to modern indicators or by the electrolytic method. Smith showed that this holds true for urines, and Hanzlik and Collins have proved it further for all body fluids. A true acid reaction occurs only in the urine and the gastric juice; the blood, cerebrospinal fluid, mucus, exudates, etc., are not acid. Therefore, no formaldehyd can be liberated in these fluids.

Another objection has been disposed of by the work of *Hanzlik and Collins*. It has been supposed that hexamethylenamin might act as an antiseptic independently of the formation of formaldehyd; these observers found that on adding this drug to various liquids inoculated with bacteria, an antiseptic effect was obtained only when a sufficient quantity of formaldehyd was liberated. If the liberation of formaldehyd in the culture mediums was prevented, even very high concentrations of hexamethylenamin were ineffective.

There remains a third theoretical possibility to be investigated. Hanzlik and Collins suggest that the reaction of the body-fluids might change to acid in disease. This is, however, highly improbable. It may therefore be affirmed that under ordinary conditions the only part of the body in which hexamethylenamin may be expected to exert an antiseptic action is the urinary tract. Extensions of the use of hexamethylenamin therapy to other organs must be abandoned as useless. Even as a urinary antiseptic, the drug is useless unless the urine is acid; if it is not already acid, sodium acid phosphate should be administered to render it so. Substances which tend to render urine alkaline are physiologically incompatible with hexamethylenamin, and, if administered in sufficient quantity to overcome the acidity of the urine, will entirely destroy the effect of the latter drug. Sodium or potassium citrate or acetate may be used in this way to stop the action of the drug if urinary irritation appears.

STARVATION METABOLISM IN INFANCY

For many years the study of the transformation of matter and energy during hunger has commanded attention because of the belief that statistics thus derived represent the basal needs, so to speak, of the organism, and furnish an index to its fundamental requirements. The expenditures of the body during periods when food is not supplied were quite naturally regarded as a measure of the real wear and tear and the demands of maintenance, independent of external factors like food. They were believed to determine in a precisely estimated way what contributions the fundamental up-keep of the human machine calls for.

More recently, numerous careful investigations have placed new interpretations on the nutritive phenomena of inanition. They have forced to our attention the fact that metabolism in starvation shows deviations from the nutritive exchanges in ordinary conditions of health and adequate diet. Indeed, it is no stretch of truth to designate certain features of hunger metabolism as akin to those commonly regarded as pathologic in type. We need only recall here the acidosis phenomena which speedily manifest themselves when an individual is completely deprived of food. The full significance of all that is involved still needs to be learned; and this deserves emphasis in view of the wide-spread propaganda for so-called fasting cures fostered by untutored faddists and promulgated by all manner of publications that catch the public eye. The harm that is threatened needs equally well to be brought to popular notice, despite the fact, which may freely be admitted, that enforced starvation can have useful applications in therapy. The advisability of a measure not infrequently depends on the person who is to administer it; and for the present dietotherapy is surely safer in the hands of experts in nutrition than in those of routine magazine writers.

[1] Hanzlik, Paul J., and Collins, R. J.: Hexamethylenamin: the Liberation of Formaldehyd, and the Antiseptic Efficiency under Different Chemical and Biological Conditions, Arch. Int. Med., November, 1913, p. 578.

The institution of starvation, either complete or partial, has obtained some recognition of late in the clinic of the disorders of early infancy. If opinion has been somewhat divided among the experts as to its advantages or counter-indications, this is doubtless due to the fact that comparatively little has hitherto been known in regard to the hunger metabolism of normal individuals at this early period of life. The rapidly progressing modern pediatrics has appreciated the gap in our knowledge and is seeking to fill it with first-hand information. The work of Schlossmann's clinic in Düsseldorf may be singled out to illustrate the newer acquisitions in this field.[1] It is made evident by the most recent of these studies that the loss of nitrogen in starving normal infants is of about the same order of magnitude, per kilogram of body weight, as that of adults during inanition. The individual variations exhibit a comparable range. In infants the protein metabolism of starvation appears to be pronouncedly dominated by the preceding type of nutrition. If this has been rich in albuminous foodstuffs, the nitrogen output in the early days of starvation will be correspondingly high. This is no new fact in the science of nutrition; but it is worthy of emphasis here because of its practical aspects in the case of infants. Breast-fed children usually transform less protein than do infants on "artificial" dietaries; they likewise disintegrate less of their own protein when starvation is inaugurated. Schlossmann maintains that if, for any reason whatever, a breast-fed child is forced to starve, it will be likely to survive the hunger with far less loss and nutritive damage than artificially nourished infants would undergo.

The excretion of the ketone substances—acetone, beta-oxybutyric acid—appears to be comparable, in the case of infants, to what obtains in adult man. There is no doubt that lack of carbohydrate, i. e., carbohydrate starvation, is the underlying cause. In other details, too, the hunger metabolism of infants at rest tallies with what previous physiologic studies lead one to expect. Such facts must form the basis for any judgment as to the utility or consequences of procedures which involve starvation during infancy.

ABERRANT EPITHELIAL STRUCTURES IN THE CORTEX OF THE KIDNEY AND THEIR RELATION TO THE SO-CALLED HYPERNEPHROMA

The so-called hypernephroma is undoubtedly the most frequent malignant tumor in the kidneys. Until quite recently these tumors were regarded as originating in aberrant remnants of adrenal tissue most commonly believed to occur immediately under the capsule of the kidney. This view was advanced by Grawitz in 1883, and the tumors in question are frequently referred to as "Grawitz tumors." This conception of the origin of these tumors was based largely on the similarity between the tumor cells and the cells in the adrenal cortex. Specks and patches of a yellowish or grayish-yellow paler than the renal cortex are frequently found in the surface of the kidney, and these structures are held, usually, to be bits of misplaced adrenal tissue. Renal hypernephromas consequently have been regarded as a good illustration of Cohnheim's supposition that malignant tumors develop from misplaced embryonal matrix, a conception of which we hear much less now than we did some years ago.

Of late the view of Grawitz in regard to the nature of the so-called hypernephromas has been attacked by various men. Thus Stoerk pointed out that such growths do not occur in the adrenals, the primary tumors of which are of different structure, and that the most common site of the Grawitz tumor is the middle zone of the kidney; whereas the supposed adrenal rests most often occur near the upper pole of the kidney. Wilson and Willis[1] regard the hypernephromas as developing in rests of nephrogenic tissue; they base this conclusion on elaborate embryologic considerations, and Glynn[2] emphasized that, while abnormal sexual development is frequently present in cases of tumors of the adrenal cortex, it is not observed in cases of Grawitz tumor.

In view of all this opposition to Grawitz' explanation it becomes a matter of importance to subject the peculiar patches in the renal cortex just mentioned to closer study in order to understand their true nature better, and from Dunn's[3] observations on eighty consecutive post-mortems we learn that such masses are, in the first place, not at all infrequent (as is already known), and, furthermore, that they represent three distinct types, namely, true adrenal rests, adenopapillary tissue and papilliferous cysts. The cells in the latter in particular resemble the bloated cells of the Grawitz tumor and, while malignant growths may be conceived to arise from any and all of these formations, "the papilliferous, from their peculiar histologic features, suggest themselves as the most probable origin of tumors of the Grawitz type" (Dunn). These cysts appear to originate from the tissue of the kidney and in one case Dunn was able to trace a definite connection with a convoluted tubule.

[2] Glynn, E. E.: Adrenal Cortex, Its Rests and Tumors; Its Relation to Other Ductless Glands and Especially to Sex, Quart. Jour. Med., 1912, v, 157; abstr., The Journal A. M. A., Dec. 7, 1912 p. 2097.

[3] Dunn: Jour. Path. and Bacteriol., 1913, xvii, 515.

These results indicate that further systematic studies of so-called adrenal rests in the kidneys are desirable, and that additional insight may be secured thereby into the nature and origin of malignant tumors of the kidney.

PHTHISIOPHOBIA IN THE LIGHT OF RECENT DEVELOPMENTS IN TUBERCULOSIS INVESTIGATIONS

With the application of our growing knowledge of the immunologic reactions to tuberculosis, and especially the influence of allergy on the tuberculous process, have come new concepts and revivals or transformations of old ones. The studies of von Pirquet, Roemer and Hamburger, the workers in the laboratories at Saranac Lake, Calmette and others, have thrown a new light on the relation of allergy to tuberculosis and the nature of reinfection and superinfection. They show that what has been recognized clinically as a lowered resistance to tuberculosis, as after measles, influenza, etc., is undoubtedly associated with the condition of allergy of the person. Thus, von Pirquet found that in measles there may be a disappearance of an existing tuberculin sensitiveness during the height of the acute disease, with a return of the reaction later. Now since practically all persons become infected with tuberculosis in childhood, and become allergic to the tubercle bacillus so that they give positive tuberculin reactions, it is evident that the existence of the original latent or healed lesion and the resulting allergic condition must profoundly modify subsequent infection with new strains of tubercle bacilli which are introduced from time to time during the rest of the person's life.

Many experimenters have shown that a previous infection does serve to protect against infection with new lots of tubercle bacilli, and this principle is now generally accepted. Thus, a guinea-pig already infected with tubercle bacilli successfully resists subsequent local inoculations, not only with tubercle bacilli from outside sources but also with bacilli cultivated from its own lesions. As to the influence of this principle on human tuberculosis, and especially on the danger of infection from consumptives, we would commend to our readers an address on this subject by Dr. E. R. Baldwin of Saranac Lake.[1] He points out the need of applying a check to phthisiophobia, which "has had no check from the time the knowledge of the bacillus was popularized. Cornet's dust experiments first gave the impulse to a fear, followed by Flügge's droplet infection, which has aggravated the solicitude felt by physicians and nurses, and which has been gradually spread to the laity." Not until the recent researches, briefly considered in the foregoing, have we had a proper understanding of the great power of defense of which the average adult is capable, although not a few careful clinical observers have pointed out evidence that the constantly exposed husbands and wives with consumptive mates show no such morbidity as a high degree of contagiousness would necessarily produce, and the incidence of tuberculosis in physicians and nurses in tuberculosis hospitals is not indicative of a ready infection with the omnipresent bacilli.

Baldwin says that we are reasonably sure of the following: 1. Most adults have received some tuberculous infection. 2. From this they have acquired a variable degree of specific allergy. 3. During ordinary health the tissues repel tubercle bacilli, partly, at least, with the aid of this specific allergy. 4. Reinfection of adults is mostly a superinfection coming from the existing lesions, and due to disease, trauma, overstrain or any cause of "lowered vitality," whatever that may mean. 5. "Finally, as a corollary, adults are very little endangered by close contact with open tuberculosis, and not at all in ordinary association. Childhood is the time of infection, youth the time of superinfection, and that from extension of the primary disease. Qualify these statements as we may, it is time for a reaction against the extreme ideas of infection now prevailing. There has been too much read into popular literature by health boards and lectures that has no sound basis in facts, and it needs to be dropped out or revised. More protection of children and better hygiene for adults are logically demanded, but beyond this the preachments about the danger of infection to adults in the present state of society are without justification from an experimental standpoint." The statements which we have quoted represent not one man's views, but what seems to be the growing conviction of many of the most progressive and thoughtful students of tuberculosis at the present time.

Current Comment

DEFICIENT OXIDATION AND NARCOSIS

We have in the past discussed the broad and mooted question as to whether the manifestations of narcosis are due to a sort of asphyxiation of the cells — in other words whether deficient or decreased oxidative capacity can explain the familiar narcotic phenomena of the nervous system.[1] The view that organic narcotics and anesthetics of the volatile type bring about an insensibility or decreased irritability toward stimuli primarily by depressing the rate of oxidative changes in the tissues has been vigorously defended. Equally trenchant have been the criticisms directed against the theory. We mentioned some of these in referring to Winterstein's important observation that certain parasitic animals which are capable of undergoing an existence in the absence of respired oxygen are nevertheless readily narcotized by the volatile anesthetics — a fact which would be inexplicable on the assumption that narcosis is due to an inhibition of oxidation.[2] Further convincing evidence has now been furnished by Loeb and Wasteneys.[3] In varied selected experiments on lower forms in which the numerous accessory disturbing factors offer less interference in drawing a clear-cut conclusion, the investigators of the Rockefeller Institute have shown that conditions of profound narcosis can be induced without any noteworthy diminution of the normal rate of oxidation for the species. Furthermore, though an inhibition of motility and irritability to stimuli can be brought about by decreasing the oxidative changes—for example, by cyanids—the narcotic phenomena are not manifested by this means until the oxidative functions are lowered far beyond the point reached in ordinary narcosis with substances like chloroform, ether, alcohols, chloral hydrate, urethane, etc. Conversely, in order to depress oxidation these compounds must be administered in concentrations far beyond that called for in the purposes of narcosis. The asphyxial theory of narcosis seems doomed.

DEATHS OF CHILDREN BY BURNING

While fatalities from burning are but a minor fraction of the mortality from preventable causes, they are sufficiently numerous to warrant an attempt to prevent them. This is especially true of deaths of children from burning. In this country there are few available correct statistics on the subject. In England, however, it is different; there the statistics are not only dependable, but available. Dr. Brend[4] has compiled and analyzed the data regarding deaths of children from burning. From the years 1906 to 1911 he found that up to the age of 1 there were 214 boys and 234 girls burned; from 1 to 4, there were 1,663 boys and 1,818 girls; from 4 to 5, 368 boys and 775 girls; from 5 to 10, 389 boys and 1,427 girls, and from 10 to 20, 80 boys and 630 girls. It is at once evident that there is a marked difference between the mortality of boys and girls. This difference is probably due to the different type of clothing worn by the two sexes. Up to about the ages of 2 and 3, boys and girls are dressed alike. From 3 to 4 the boys put on the simpler male attire and there is an abrupt and marked fall in the mortality from burning. There has been much condemnation of the material known as flannelet, which is a very inflammable cloth, although from the figures quoted it would seem that it is not so much the material as the style of clothing which leads to loss of life. For other reasons as well, namely, freedom of movement, better hygiene and general cost of clothing, there would seem to be a demand for a further simplification of the manner of dressing girls, particularly those of the younger ages.

HYDROXYPHENYLETHYLAMIN — AN ANIMAL POISON

The pharmacologic investigation of synthetic aromatic amins has been greatly stimulated by the discovery of the chemical structure of epinephrin and the demonstration that it belongs in this group of organic compounds. The systematic testing of numerous related and suitably constituted amins has shown that in general they exhibit pressor effects on the circulation and other physiologic phenomena characteristic of the effective agent of the adrenals, their activity increasing according as they approach the chemical structure of epinephrin. One of the most interesting of all these newly investigated products is hydroxyphenylethylamin, which can readily be prepared from the protein cleavage derivative tyrosin by splitting off carbon dioxid from the molecule of the latter. This reaction can be brought about by putrefactive bacteria; and in truth hydroxyphenylethylamin has been detected among the products of the putrefaction of proteins and identified by Barger among the pressor principles yielded by putrid meat.[1] The same base was found by Barger to be responsible for some of the characteristic physiologic activities of ergot preparations.[2] Unexpected evidence that hydroxyphenylethylamin can actually arise as a product of metabolic transformation in animal organisms has arisen in the unique discovery by Henze in Naples that the poison secreted by certain cephalopods is in fact this aromatic organic derivative of tyrosin.[3] It is well known that in catching their prey cephalopods make use of a highly active poison which is produced by the so-called salivary glands of these invertebrates. Crabs, which they are prone to attack, are speedily impaired by this glandular poison, which was formerly erroneously believed to be of the nature of a toxalbumin. Nothing could be more illustrative of the great progress of biochemistry in recent years than the interesting relationships which it has revealed. Meat rots and yields a putrefactive product that is toxic, that is, produces with small doses marked physiologic manifestations; ergot develops as the result of growth and furnishes the same compound, long devoted to pharmacologic uses; and the glandular tissues of animals which poison their prey secrete it likewise. In each case we may easily assume that it has arisen by simple chemical reaction from the proteins, the fundamental step being imitated by the chemist when he in turn prepares the same substance in his laboratory from the innocuous tyrosin. Our poisons and our drugs are in many instances the close relatives of the harmless compounds that represent the intermediate steps in the daily routine of metabolism.

FOREIGN COMMENT ON THE FRIEDMANN TREATMENT

German medical journals seldom express opinions on any question, and still less frequently, for some reason, on therapeutics. It is, therefore, worthy of note that the Friedmann remedy has called forth a warning from one journal, the *Therapie der Gegenwart.* A recent issue[1] contains a critical review by F. Klemperer, of the so-called clinic conducted by those favoring the Friedmann treatment, a report of which has been widely circulated in this country. In connection with the publication of Klemperer's article, the editor says:

> I have received a large number of inquiries asking whether I advise the use of Friedmann's remedy in general practice. I consider it a duty, therefore, not to refrain from stating my personal stand on the question. According to my opinion, general practitioners as yet have no occasion to use the new remedy in their practice. The method can by no means be regarded as having been tested; all the commendation of it proceeds from one side. Those who lived through the tuberculin era and have watched the development of tuberculin since will tranquilly wait. Personally I do not regard its theoretical foundation as by any means sufficiently established. I do not regard it as necessary to explain my theoretical hesitation any further, the more so as the decision as to the value or worthlessness of the remedy will in a reasonable time be determined by the therapeutic trials, which will now be instituted everywhere in hospitals and clinics. The task of trying out the new remedy under calm observation belongs to these institutions. It is not yet ripe for general practice, and the general practitioner can incur no reproach if he holds aloof for the present.

In view of the extreme reluctance on the part of German journals to say anything derogatory regarding German products, the caution quoted above is significant.

PARTICIPANTS IN FRAUD

This is from an editorial, "Square Deal Advertising," in the Chicago *Tribune,* December 19:

> The paper that sells publicity to a known fraud is a partner in the fraud, and deserves to be punished for its part in the fraudulent transactions in the profits of which it participates. Against their joint deceit the public ought to be protected.

This quotation is respectfully referred to the two hundred and fifty medical journals in the United States that "sell publicity" to manufacturers of products that have been shown to be absolute frauds.

HONEST CRITICISM WELCOME

It sometimes happens that a good paper offered for publication is returned and one not so good is accepted. Often, to the minds of individual readers, an editorial strikes a discordant note. The proceedings of one society seem to receive undue attention, and those of another, perhaps more important, too little. The abstracters for the Current Literature Department, examining hundreds of journals monthly, at times slight an issue of one journal and give disproportionate space to another. All these things at times occur, for none among us is exempt from his share of human imperfection. Almost as soon as we have noted our own slip or error, the criticisms begin to reach us, some with harsh censure and satire, and some with helpful and kindly words. Even from the bitter husk of the hastiest and most virulent invective we try to extract the kernel—if there be any—of sound criticism. But, like the rest of humankind, we give most heed to and gain most help from fair-minded criticism, written in a kindly spirit of helpfulness and with an evident desire to aid. To the writers of such comments we owe hearty thanks. They are an inspiration to work and a stimulus for continued endeavor to do the best we can to meet the needs of all.

Medical News

ALABAMA

Personal.—Dr. Samuel F. Nash, surgeon of the Southern Steel Company at Virginia Mines, has resigned and located at Bessemer.——Dr. Francis A. Webb, Calvert, who has been ill at the Mobile Infirmary, is reported to be improving.

Hospital News.—Cunningham Hospital, Ensley, has been leased by the Tennessee Coal, Iron and Railroad Company which will employ its own physicians and conduct the institution.——Plans for the erection of a hospital at Ensley were decided on November 28 at a meeting of physicians at which a hospital organization was formed with Dr. William H. Wynne as chairman and Dr. Merit D. Clements as secretary.

New Officers.—Walker County Medical Society at Jasper, December 12: president, Dr. Allen M. Waldrop, Cordova: secretary-treasurer, Dr. James L. Sowell, Jasper.——Mobile County Medical Society at Mobile, December 13: president, Dr. Ruffin A. Wright; secretary-treasurer, Willis W. Scales (reelected), both of Mobile.——Marengo County Medical Society at Linden, December 13: president, Dr. James B. Whitfield, Demopolis; secretary, Dr. Guy J. Dunning, Linden.——Colbert County Medical Society at Tuscumbia, December 13: president, Dr. William H. Greer; secretary-treasurer, Dr. Julius T. Haney, both of Tuscumbia.——Bibb County Medical Association at Centerville, December 12: president, Dr. M. C. Thomas, West Blockton; secretary-treasurer, Dr. Horace L. Cunningham, Centerville.——Barbour County Medical Association at Eufaula, December 12: president, Dr. W. R. Belcher, Baker Hill; secretary-treasurer, Dr. Joseph W. Fenn, Eufaula (reelected).——Chambers County Medical Society at Lafayette, December 11: president, Dr. Benjamin F. Rea, Jr. (reelected).

ILLINOIS

Society Scores Quacks.—At the regular bimonthly meeting of the Rock Island Medical Society held in Rock Island, December 9, resolutions were adopted endorsing the publicity campaign directed against quacks and quackery and disapproving of the publishing of physicians' names in connection with accident, operations and other medical work.

Personal.—Dr. Daniel Lichty has been elected president, Dr. Harry A. Pattison, secretary, and Dr. William E. Park, treasurer of the Rockford Public Tuberculosis Hospital trustees.——A farewell reception was given Dr. and Mrs. George A. Zeller at the Peoria State Hospital, December 18.——Dr. Fred G. Warner, Grafton, has been appointed surgeon in Jersey County for the Mississippi Power and Transmission Company.

State Health Board Attorney Shot.—The members and officials of the State Board of Health have frequently been threatened, but on December 4, Charles Alling, attorney for the board, was shot in his office in Chicago by a man who had been convicted three times of practicing medicine without a license and who afterward killed himself. Mr. Alling's injuries necessitated the removal of the right eye and he is now said to be doing well.

Civil Service Commission Medical Board.—The State Civil Service Commission has named a permanent medical board to have charge of its medical examinations in the future. The board consists of Dr. James B. Herrick, Chicago, chairman; Drs. Thomas H. Culhane, Rockford, and Dean D. Lewis, Chicago, surgery; Drs. George F. Suker and William D. Napheys, Chicago, medicine; Dr. Ludvig Hektoen, Chicago, pathologist, and Drs. James C. Gill and L. Harrison Mettler, Chicago, and Harold D. Singer, Hospital, nervous and mental diseases.

---

[1] December, 1913, p. 537.

New Officers.—Alexander County Medical Society at Cairo, December 18: president, Dr. Samuel Dodds; secretary-treasurer, Dr. James W. Dunn, both of Cairo.——Danville Physicians' Club, December 18: president, Dr. Elbert E. Clark; secretary-treasurer, Dr. Otto H. Crist.——Streator Medical Association, December 18: president, Dr. George K. Wilson; secretary, Dr. F. Lloyd Bronson, Streator.——Will County Medical Society at Joliet, December 17: president, Dr. Aloysius J. Lennon; secretary-treasurer, Dr. Marion K. Bowles, both of Joliet.——Peoria City Medical Society, December 16: president: Dr. Sumner M. Miller; secretary, Dr. Elbert W. Oliver *(reelected)*.——Whiteside County Medical Association at Morrison, December 11: president, Dr. Herbert Leroy Pettitt, Morrison; secretary-treasurer, Dr. Francis J. Conroy, Sterling.

Chicago

Praise for Administrative Officer of Hospital.—A dinner was given in honor of Albert M. Day, president of the board of managers of the Presbyterian Hospital by the medical staff of the institution, December 22, to celebrate the completion of the additions and enlargements of the hospital. During the proceedings, an oil portrait of Mr. Day was presented to the hospital managers by the staff. Addresses eulogistic of Mr. Day were made by Drs. Frank Billings, J. Clarence Webster and Ludvig Hektoen, Rev. John T. Stone and Mrs. Helen McMillan.

Three Isolation Hospitals Planned.—The propaganda committee of the Chicago Medical Society proposes the erection of three new contagious disease hospitals to be located on the south, north and northwest sides of the city, respectively. It is proposed to make a charge for patients able to afford to pay for hospital service. The first step in the education of the public suggested by the committee is lectures in schoolhouses and churches, where members of the society will discuss health subjects with the people and answer questions that may be asked.

MAINE

Personal.—Drs. Harold J. Everett, Philip P. Thompson and Alfred Haskell have returned from Europe.

Sanatorium Burned.—The sanatorium of the Bangor Anti-Tuberculosis Society, 2 miles from the city, was totally destroyed by fire with its contents, December 1, with a loss of $5,000.

New Officers.—Cumberland County Medical Society, December 19: Dr. J. Madison Taylor, Philadelphia, read a paper on goiter; Dr. Bertrand F. Dunn was elected president and Dr. Adam P. Leighton, Jr., Portland, secretary.——Knox County Medical Society at Rockland, December 10: president, Dr. F. B. Adams; secretary-treasurer, Dr. H. W. Frohock, South Thomaston.

NEW YORK

Hospital Quarantined.—The Nassau Hospital at Mineola, L. I., has been under quarantine for the past week owing to an outbreak of diphtheria among the patients and nurses. The disease is said to be under control and the quarantine will probably be raised within a few days.

Prize Essays.—The committee on the award of the Merrit H. Cash prize, which is awarded every two years to a member of the Medical Society of the State of New York, announces that this prize will be awarded in 1914.——The Lucien Howe Prize amounting to $100 each year. The essay must be on a subject pertaining to ophthalmology. The essays must be sent to Dr. Albert Vander Veer, 28 Eagle Street, Albany, N. Y., not later than March 1, 1914.

Unique Method of Making Milk Examinations.—The *Monthly Bulletin* of the New York State Department of Health contains the Rochester Health Report for the year 1912 in which a unique method of recording milk examinations is described. It is the work of Dr. George W. Goler, Rochester, and is as follows:

> Disks of cotton containing the sediment are placed in the covers of the original tin boxes in which they are collected. The cover has the name of the producer, date of collection and name of retailer on it. The boxes with their contents are dried in the incubator and are then pasted on rectangular sheets of glass 8½ by 6 inches. These sheets of glass are then filed in a specially made filing cabinet, each retailer having his producers filed on one or more sheets of glass. A tally-book serves to show the number of the retailer and his list of producers. At the outside of the health office is an iron cabinet with a glass front in which a number of these glass slides are posted, and those interested are invited to inquire at the health office for their milkman's record. When an inquiry is made, not only the cotton disk with the sediment is shown, but the report of his dairy, his producers, the bacteriologic count, the temperature of his milk; in fact, his whole record is exhibited to the inquiring consumer.

New York City

Harvey Society Lecture.—The next lecture in the ninth course of Harvey Society lectures will be given at the New York Academy of Medicine, January 17, when Prof. Victor C. Vaughan, University of Michigan, will lecture on "The Etiology of the Infectious Diseases."

Insurance Company Opens Sanatorium.—The Metropolitan Life Insurance Company has opened its new sanatorium for the care of employees afflicted with tuberculosis. The institution is located at Mount McGregor, N. Y., 1,200 feet above sea level on a site embracing 420 acres.

Social Service Work for State Hospital.—Funds have been secured for the establishment of a social service department in connection with the Long Island State Hospital for the Insane, Brooklyn, N. Y. A social worker has been employed for the purpose of preventive care and "follow-up" work among the insane in the City of Brooklyn.

New Hospital Opened.—The new Herman Knapp Memorial Eye Hospital at Fifty-Seventh Street and Tenth Avenue, which houses the old New York Ophthalmic and Aural Institute which was founded by Dr. Knapp in 1869, was opened December 12. The building is seven stories in height and is the last word in hospital architecture and equipment that science and money can provide. The building was constructed by the trustees in memory of Dr. Knapp by funds collected for that purpose.

Municipal Health Exhibit.—The Department of Health opened its first permanent municipal health exhibit in this city, December 17, on the fifth floor of the Health Department building. The exhibit had its origin in the budget display of last year and consists of displays showing the work of the various bureaus of the Health Department, among them being a children's hospital ward and one of the tuberculosis sanatorium at Otisville. Among speakers on this occasion were Dr. Stephen Smith, health commissioner from 1868 to 1875; Dr. Abraham Jacobi and Prof. Charles F. Chandler, commissioner from 1879 to 1883.

Social Hygiene at Columbia.—The first report of an investigation that has been in progress for a year in regard to the sanitation, food and social hygiene of students has been presented by Dr. William H. McCastline, the health officer of Columbia University. The report shows that there have been few cases of contagious or infectious disease and that the number of students who have been willing to come for consultation in regard to moral problems is most gratifying. It is affirmed that as a class Columbia men are of excellent principle and high moral caliber. Dr. McCastline has organized a student board of health, whose duty shall be to improve the eating houses and restaurants in the vicinity of the University. Two courses in social hygiene have been arranged, one for the freshman year, which shall cover all the facts that a young man should know in relation to personal and social hygiene, and one for the senior year which shall have for its object the presentation of facts that will enable the men to appreciate their obligations as men to society and the home.

NORTH CAROLINA

New Officers.—Buncombe County Medical Society's eighteenth annual meeting at Asheville, December 15: president, Dr. Paul H. Ringer; secretary-treasurer, Dr. Gaillard S. Tennent, both of Asheville.

Patients Erect Monument to Physician.—From the voluntary offerings of former patients in the community in which he practiced in Sampson County, a handsome monument has been erected to Dr. Charles S. Kerr, Kerr, N. C., who died two years ago.

Personal.—Dr. Lucius N. Glenn, Gastonia, has been appointed a director for the City Hospital for the Insane, Morgantown.——Dr. H. L. Pitman has returned to Fayetteville, where he will be associated with Dr. Jacob F. Highsmith and will take charge of the laboratory and electrical work of the Highsmith Hospital.

PENNSYLVANIA

Antispitting Campaign.—Members of the Women's Health League of Pittsburgh were stationed in the principal streets December 19, to enforce the antispitting ordinance. Arrests were made of all offenders. This ordinance was passed several years ago, and in spite of signs on every block, has never been observed.

New Officers.—Carbon County Medical Society: president, Dr. Lewis W. Moyer, East Mauch Chunk; secretary, Dr. Calvin

J Billiet, Lehighton ——At the annual meeting of the Bucks County Medical Society, November 12 president, Dr William C LeCompte, Bristol, secretary treasurer, Dr Anthony F Myers, Blooming Glen

Personal—Dr Frederick W. Brown has been elected mayor of Franklin ——Dr Gregg A Dillinger was recently elected a member of the city council of Pittsburgh ——Dr Samuel A Woods, Sharon, who was recently operated on, is recovering ——Dr George W Kennedy, Sharon, was recently operated on for a stone in the kidney in Cleveland

Coatsville Water-Supply Held Up—The plan to establish in Coatsville a modern water supply, which was voted for by the taxpayers in August last, and to cost $185,000, has been held up by the State Health Department The reason for this delay is due to the fact that the authorities at Coatsville did not consult nor have the approval of the State Health Bureau of their plans for the new department

Philadelphia

Election of Officers—Kensington branch of the Philadelphia County Medical Society vice president of the county society, Dr Edwin B Miller, chairman, Dr William T Dempsey, clerk Dr Harry W Goos

Personals—Dr James T Rugh has been appointed Orthopedic Surgeon to the North American Sanitarium, Atlantic City, N J ——Dr William C Posey, who has been suffering with pneumonia, has sufficiently recovered to go to Lakewood, N J, for convalescence

Center of Opium Traffic Discovered—Wholly by accident the headquarters of the opium traffic in Philadelphia were uncovered at Ninth and Vine Streets There were confiscated more than $1,500 worth of raw opium and more than $100 worth of prepared opium, and two men were placed under arrest

Memorial Fund for Lectures—A fund of $10,000 has been given to the College of Physicians for the purpose of offering prizes and establishing courses of lectures on original research in medicine This fund is given as a memorial of the late Dr Nathan Lewis Hatfield The trustees of the fund are Drs Robert G LeConte, Norton Downs and Francis R Packard

Additions to Hospitals—The Lebanon Hospital Association has purchased the premises 1728, 30, 32 N Seventh Street, lot 65 by 82 feet for a consideration of $1,100 ——A contract has been awarded for alterations and additions to St Joseph's Hospital at Seventeenth and Girard Avenue ——Plans are being prepared for additions to the Garretson Hospital at Eighteenth and Hamilton Streets

To End Dispensary Graft—The Philadelphia County Medical Society and the Philadelphia County Homeopathic Society have united on a plan to wipe out free hospital and dispensary abuse Statistics from hospital and dispensary reports show that last year 530 000 patients received free treatment in Philadelphia At a meeting of the two medical societies next week a more definite plan will be decided on Already Jefferson and Hahnemann Hospitals have appointed committees to frame prevention methods

Hospitals Reform Throughout Philadelphia—Forty physicians, lawyers and business men attended a meeting in Director Joseph S Neff's office in City Hall, December 10, for the purpose of uniting the fifty five hospitals and dispensaries of the city in the adoption of an efficiency program It was pointed out that the cost of maintenance could be reduced about $200 000 by the adoption of such a program Those present subscribed liberally toward the $7,000 fund to be raised for the purpose of making an efficiency study of the whole hospital situation This movement of the County Medical Society Commission aims to "outline and chart the proper organization and management of a Central Record Bureau, with subdivisions covering general efficiency departments accounting bureaus, office methodizing departments, purchase testing and employment bureaus" Perhaps it would be well to make this bureau in addition, a 'clearing house" as to worthiness of all claimants for free treatment at all hospitals and dispensaries of this medical center Free treatment of those able to pay adds enormously toward the present financial waste in hospitals in the city

GENERAL

Fraternity Election—Dr Lewellys F Barker, Baltimore, and Dean John L Heffron, Syracuse, N Y, have been elected directors of the Alpha Omega Alpha Medical Scholarship Society The directors have elected Dr. Russell Burton Opitz, New York City, president, and Dr G Carl Huber, Ann Arbor, Mich, vice president Dr William W Root, Slaterville Springs, N Y, continues as permanent secretary treasurer

Western Surgical Association—The twenty third annual session of the Western Surgical Association was held in St Louis, December 19 and 20 under the presidency of Dr Jabez N Jackson, Kansas City, and the following officers were elected president, Dr Byron B Davis, Omaha, vice presidents, Drs Leonard Freeman, Denver, and L W Littig, Davenport Iowa, secretary treasurer, Dr Arthur T Mann and executive committee, Drs Jabez N Jackson, Amos W Abbott, Minneapolis, John P Lord, Omaha, and Malcolm L Harris, Chicago

Seaboard Physicians Hold Meeting—The eighteenth annual meeting of the Seaboard Medical Society of Virginia and North Carolina was held in Norfolk, Va, December 10 and 11 Goldsboro, N C, was selected as the next place of meeting and the following officers were elected president, Dr J Ramey Parker, Goldsboro, N C, vice presidents, Drs George K Vanderslice, Phoebus, Va, Cicero F Griffin, Winton, N C Robert F Whitehead, Kempsville, Va, and W J Harrell, Aulander, N C, secretary, Dr Clarence Porter Jones, Newport News, Va, treasurer, Dr George A Caton, Newbern, N C, and orator, Dr James H P Culpepper, Norfolk, Va

Southern Surgeons Meeting—The twenty sixth annual meeting of the Southern Surgical and Gynecological Association was held in Atlanta, December 16 to 18 under the presidency of Dr John Young Brown, St Louis Asheville, N C, was selected as the next place of meeting and the following officers were elected president, Dr John Wesley Long, Greensboro, N C, vice presidents, Drs Arthur Carroll Scott, Temple, Tex and James F Mitchell, Washington, D C, secretary, William D Haggard, Nashville, Tenn (reelected), treasurer, Dr Le Grand Guerry, Columbia, S C (reelected), and council Dr Stuart McGuire, Richmond, Va, Bacon Saunders, Fort Worth, Tex, Rudolph Matas, New Orleans, John M T Finney, Baltimore, and John Young Brown, St Louis

Warning—At this time of the year the ubiquitous subscription swindler is abroad working a nefarious game in making collections from unsuspecting victims, as payment for renewed subscriptions Information has been received that certain individuals are working the medical profession in Ohio Indiana and Tennessee By next week these swindlers will probably have migrated to some other territory Our readers are therefore cautioned to pay money to no one unless the proper credentials are produced Letters of authority bearing the signature of George H Simmons and the official seal of the American Medical Association are supplied to the A M A's representatives The holders of such letters are the only ones authorized to make collections Information by telegraph regarding any of these swindlers will be welcome

Bequests and Donations—The following bequests and donations have recently been announced

Methodist Hospital, Philadelphia $5,000 by the will of George W Fees

United Hebrew Charities and Mount Sinai Hospital New York City each $10,000 Home for Aged and Infirm Hebrews and Montefiore Home, each $2 500, St Johns Guild and Presbyterian Hospital each $1 000 by the will of Samuel H Spingarn

Little Sisters of the Poor of St Francis Society of St Vincent de Paul New York City, Sanitarium Gabriels Gabriels N Y, The Servants for the Relief of Incurable Cancer and Seton Hospital Spuyten Duyvil each $5 000 by the will of Francis Higgins

Nyack (N Y) Hospital, $5 000 by the will of Nicholls B Cushing

French Hospital New York City $1,000 for the support of a bed, by the will of Mrs J H Bacigalupo

Montefiore Home $4 500, Mount Sinai Hospital, New York City $2 500 by the will of William Scholle

United Hebrew Charities Hebrew Orphan Asylum Mount Sinai Hospital Montefiore Home, and Visiting Guild for Crippled Children New York City each $5 000, St Johns Guild and Association for Improving the Condition of the Poor, each $4 000 by the will of the late Ferdinand Hermann

Presbyterian Hospital New York City in gratitude for the care of his late wife, a residuary bequest of $75,697 by the will of Edward O Kindberg

Childrens Free Hospital Louisville and Kentucky Society for the Study and Prevention of Tuberculosis each about $5 000 and Babies Milk Fund of Louisville, $2 000 under the will of Samuel K Bland

CANAL ZONE

Personals—Dr Charles E Phillips, Ancon, formerly chief of the surgical clinic in Colon Hospital, has resigned to take up private practice in Los Angeles ——Dr John P Bates, district physician at Ancon, has resigned and will practice in Greenwood, Miss ——Dr Oscar R Troje of the Ancon Hospital staff has resigned and accepted a position with the Tennessee Coal, Iron and Rail Company in Alabama ——Dr Edward P Beverly, Christobal, district physician at Corozal, has resigned to accept a position in the pension department in Washington, D C ——Dr J J McCloom of the Eye, Ear, Nose and Throat Clinic at Colon Hospital has resigned and will practice in the United States

CANADA

Provincial Medical Meeting—The annual meeting of the Ontario Medical Association will be held in Toronto May 26 to 28 The plan of making the meeting largely clinical will be adopted which was found so successful in 1912 The president is Dr Charles F McGillivray, Whitby, and the general secretary, Dr Frederick Arnold Clarkson, Toronto

Physicians Protest Against Increased Telephone Rates—Physicians in Montreal are up in arms against the action of the Bell Telephone Company of Canada raising their rates which have always prevailed, from $40 a year to $55 a year They intend carrying their grievance before the Canadian Railway Commission at its Montreal sitting, January 5

Typhoid at Windsor, Ontario—Notwithstanding the chlorin treatment of the water supply of Windsor, the typhoid incidence shows no abatement and the city is threatened with an epidemic For the past three or four years the annual number of cases in the city has been about fifty and in the county fully one half of that number This indicates that the source of the water supply is getting worse year by year and that the greatest care should be exercised in chlorination as otherwise a serious outbreak may be precipitated at any moment

Health Officers Busy—Dr J W S McCullough chief health officer of Ontario, has received reports from the several officers of health allotted to different districts in the province The officer of No 7 district which is in northern Ontario, reports that he has looked after the interests of twenty eight municipalities and has traveled 35,525 miles in doing so Several epidemics had to be met in the year and many council meetings had to be attended to advise on sewage, waterworks schemes etc In addition many lectures were delivered on public health matters

Deportations—During the official year 1912 1913 Canada deported for all causes 1,281 persons For disease the number was 408, crime, 334, public charge 392, other causes 147 For tuberculosis the total number was 62, for insanity, 219 In the insane class the largest numbers were from England—69, United States, 43 and Scotland, 26 For tuberculosis the largest number, 29, was from England The total immigration in the year was 402 432 In addition to the deportations, 756 were rejected at ports of entry, and of this number, 333 were on account of disease

Headache Powders in Canada—The Department of Inland Revenue, Ottawa has recently issued a bulletin on 'headache powders" It will serve to do some good as it practically calls the attention of the public to the harm which is done by the indiscriminate use of these powders After pointing out that headache is merely a symptom of disease, the bulletin further directs attention to the fact that the efficiency of the powders is due to powerful heart depressants, capable under certain conditions to produce fatal results, and in most cases considerable harm Nearly all of 171 samples analyzed contained acetanilid or phenacetin and are so marked under the regulations of the Patent Medicine Act The amount of acetanilid present was over 3 grains Most of them also contained caffein

Inspection Tour—Dr Helen MacMurchy, the newly appointed assistant to Dr Robert W Bruce Smith, Inspector of Hospitals and Public Charities in Ontario, has returned to Toronto from a tour of inspection of the private hospitals in the province and states that this new hospital legislation has proved beneficial to the entire province One result of the legislation is a stimulation for more hospitals especially in the newer districts of the province, and a decided improvement has already taken place in the maternity branch of the work Another feature of marked benefit is the establishment of medical cabinets in districts from 50 to 100 miles from the nearest physician These embody a little more than first aid requisites but enable medical care to be given for several days and if necessary by any one who will follow the directions

To Withdraw or Not to Withdraw—Is the Ontario Medical Association to withdraw from affiliation with the national medical body, the Canadian Medical Association? At the annual meeting of the latter in London last June a notice of motion was presented which called for such withdrawal An editorial in the December issue of the *Canadian Practitioner and Review* recalls the foundation of the Ontario Medical Association in 1880, the organization at that time was opposed by the Ottawa Medical Society on the grounds that it might be injurious to the interests of the Canadian Medical Association The particulars of the grievance are that since 1910 the Ontario Medical Association has only been able to hold two annual meetings, as according to the terms of affiliation when the national medical body meets in any one province the annual meeting of the provincial body shall not be held in that year It is understood also that there has been considerable friction between the executives of the two associations over the financial arrangements In Ontario there appears to be considerable dissatisfaction with the present arrangements

Better Housing—The cause of better housing is proceeding apace in Toronto The Toronto Housing Company with 166 shareholders who have together advanced $100 000, have joined in the solution of the problem of better housing of the working people Some time ago the medical officer of health reported there were 390 houses unfit for habitation, 2,137 houses with two or more families, 198 one room dwellings, 411 two room dwellings and 646 three room dwellings The Ontario government has unanimously enacted legislation which provides a way by which the cities and towns of the province may to a large extent solve the problem of providing houses at moderate prices for their people On the passage of this legislation the Toronto city council immediately appropriated $850 000 for the purposes of the Toronto Housing Company On one block of land $55 000 has been spent in providing homes for thirty eight families Recently the corner stone was laid for the company's cottage flats in the northeastern portion of the city, while land has been acquired in the northwestern part of the city for future operations Numerous cities and towns in Ontario have begun to organize housing companies

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Dec 13, 1913

Sir William Osler on the Medical Clinic

At a meeting of the Abernethian Society at St Bartholomew's Hospital Sir William Osler delivered an address on 'The Medical Clinic—a Retrospect and a Forecast" He related his personal experiences as a clinician and showed on a screen photographs illustrating the instruction of classes of medical students at the Johns Hopkins Hospital by the examination and treatment of patients in the presence of the pupils They had to organize the hospital on Continental lines and different men were placed in charge of different departments He introduced the system of clinical clerks and dressers which is regarded here as one of the principal merits of the English system They adopted the plan of the physician in chief who had full control and appointed his senior assistant and his second and third assistants and a man in charge of the clinical laboratory That was a direct transfer of the German system When the medical school opened they took those assistants over as part and parcel of the school, and they organized the outpatient department with men who were also made teachers in the medical department It was not easy to present the work of the clinic to the students unless there was organization, and so clinical committees were appointed—three or four men who made reports on diseases Connected with the clinic there must be laboratories which must be equipped sufficiently for the students to do research work Conditions had changed and were changing There was a spirit of unrest, and the medical profession was disturbing itself The question which was worrying people in the medical schools was whether it was possible to graft on the good old English method something similar to that which had been found advantageous in the United States The teaching of medicine was too complicated now, and it was necessary to bring our university system into the hospital - We had to make medicine and surgery departments of the university, each department with a head who should manage his own department, who would have his own clinic and own assistants The speaker's attitude was not altogether favorable to the whole time clinical professor Osler would rather that the professor spent the greater part of his time on that work, and devoted a limited portion of it to his outside work But that was a problem that the next generation had to solve

New Disease in the Sudan

Dr. H. B. Fantham, in the course of a lecture delivered on Friday before the Liverpool School of Tropical Medicine, dealt with the diseases of the Anglo-Egyptian Sudan. The lecturer described his pioneer researches, in company with Dr. Chalmers and Captain O'Farrell, of the Wellcome Laboratory, Khartoum, on a form of bronchitis due to a new spirochete occurring in the respiratory passages of man. This spirochete had not before been recorded from Africa, and very little is known about it. Both natives and Europeans suffer from bronchial spirochetosis, especially after the rains. Relapses are common, but the disease is amenable to treatment. It is widespread, endemic centers having already been found at Khartoum, Omdurman, Kodok and other places.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec. 12, 1913.

Death of Dr. Empis

Dr. Empis, former agrégé of the Faculté de médecine de Paris, and former president of the Académie de médecine, has just died, aged 89 years He was one of the last representatives of that brilliant French clinical school which, toward the middle of the nineteenth century, occupied so important a position in medicine. After publishing many clinical studies on diphtheria, irregular varioles, etc., Empis published in 1865 a work in which he gave a remarkable description of the clinical picture of acute miliary tuberculosis. Two years later he published a work on the statistics of the obstetric services of the hôpital de la Pitié and the measures employed there against puerperal fever. These studies for the first time stated the problem of the contagiousness of puerperal fever and declared the necessity for isolating puerperae so affected and the necessity of using the strictest prophylactic measures against the disease Empis was elected a member of the Académie de médecine, over which he presided in 1895.

Insufficient Application of the Law with Regard to Compulsory Vaccination

Dr. Camus of the Institut supérieur de vaccine, attached to the Académie de médecine, at the last session of the academy showed some documents which showed that the law was by no means strictly enforced. The figures with regard to deaths from small-pox showed that there is a continual decrease:

1907	2,679 deaths
1908	171 deaths
1909	87 deaths
1910	78 deaths
1911	70 deaths
1912	20 deaths

These remarkable diminutions could not be altogether attributed to scrupulous enforcement of the law. We are at present getting the benefit of the protection afforded by numerous vaccinations formerly made and especially the revaccinations, regularly practiced in the army and in certain schools. Camus has found that in 1911, thirty eight departments reported a diminution of the number of vaccinations compared with the previous year, and that in 1912 sixty departments showed such a decrease. In the greater number of the departments the law is not applied as it should be, and it is less and less strictly enforced.

To prevent future epidemics of small-pox, which are to be greatly feared in a population continually less immunized, the following measures should be adopted: (1) To enlist the interest of teachers, heads of schools and managers of commercial enterprises; (2) to facilitate the vaccination of women and young girls by setting apart special rooms or hours for their vaccination, since it is among women and young girls especially that vaccination is most frequently refrained from, doubtless because of their fear of promiscuous exposure since the operation requires taking off some of the clothing; (3) to make the prefects instead of the mayors responsible for the enforcement of the law since the former are more independent and therefore in a position to enforce the law with less fear of consequences.

Divorce and Alcoholism

Dr. Ladame of Geneva recently read before the Société française d'eugénique an interesting paper on this subject. Thirty years ago he had mentioned the parallelism between suicide and divorce, which was noticed also by Bertillon and Durkheim. Ladame believes that there is a cause common to these two phenomena, that is, alcoholic intoxication. In the decrees of divorce given at Geneva between the years 1901 and 1910, it seems that, eliminating uncertain cases, out of 1,812 divorces 672, or 37.3 per cent., were caused by alcoholism or drunkenness The comparative tables of these cases of divorce show that most frequently it was the husbands who drank and that naturally it was the wives who sought divorce. The parallel between the increase of alcoholism and that of divorce in the first part of the period mentioned is apparent; on the other hand, since a tax has been put on alcohol in Switzerland, the number of divorces have diminished.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec. 5, 1913.

Personal

Professor Neumann of Giessen has accepted the call to Bonn as successor to Professor Kruse.

Professor Loeffler has been appointed a member of the Prussian state scientific deputation for medical affairs.

Professor Forschbach has been appointed director of the medical university policlinic at Breslau as the successor of Professor Ziegler, who has gone to Freiburg as director of the medical policlinic.

Professor Flechsig, director of the neurologic clinic of Leipsic, has been given leave of absence on account of illness. He will be represented in the conduct of the clinic by Privat-Docent Quensel.

Behring's New Method for Prevention and Treatment of Diphtheria

Further trials of the active immunization against diphtheria with Behring's new preventive remedy, made in the Magdeburg municipal hospital at Sudenburg, are said to have given good results. About 500 children were vaccinated by two assistant physicians of the hospital in six small cities and villages of the district in which diphtheria epidemics were prevalent. As a result, none of these children sickened with diphtheria although the endemic in these localities still continues. Some children were vaccinated only once for special reasons and of these several became ill but only within the first ten days, and among them the diphtheria ran a lighter course than in the other cases. No bad results have been observed from the vaccination in these children.

An International Medical Society in Berlin

Under the title of Internationaler Aerzteverein, an association apparently founded by Russian business men is attempting to secure foreign physicians in medical institutions for the purpose of their further improvement. To this end it is seeking to gain over the directors of foreign German hospitals to assist in its undertaking. The *Deutsche med. Wochenschrift* in its latest number warns against this organization which is evidently concerned in obtaining patients. The board of directors of the association consists of two Chilians, one Greek, one Spaniard and two Russians, none of whom apparently is a physician, and a former military surgeon in Kiev. The treasurer (!) is apparently the only German.

Medical Report on King Otto of Bavaria

Your readers are aware from the newspapers that the Prince Regent Ludwig has assumed legal power in place of the insane king, Otto, who has been deposed. The commission appointed to report on the mental condition of King Otto, consisting of Professor Kraepelin of Munich, Professor Specht of Wurzburg and some other physicians, concluded that King Otto of Bavaria was incurably insane and should be deprived of the exercise of his royal power to the end of his life.

Memorial for Robert Koch

December 11, the day on which he would have completed his seventieth year, there was instituted a quiet memorial in memory of Robert Koch by Professor Loeffler, the present director of the institute, in the Robert Koch mausoleum, which, as is well known, is located in the Institute for Infectious Diseases in Berlin The entire board of directors of the Robert Koch foundation for the campaign against tuberculosis took part in the celebration. Memorial wreaths were placed in the mausoleum by this as well as other corporations, and in honor of the memorial day the *Deutsche medizinische Wochenschrift*, the regular organ of publication of the great bacteriologist, issued a special number to which interesting contributions were furnished by the most noted pupils of Robert Koch, Loeffler, Ehrlich, Brieger, H. Kossel, Uhlenhuth, Pfeiffer, Kolle and others.

Deaths

Brigadier General George Henry Torney, Surgeon General, U. S. Army, died at his home in Washington, December 27, from bronchial pneumonia, aged 63. He was born in Baltimore, June 1, 1850, the son of John P. and Mary M. Peacock Torney. He received his preliminary education at Carroll University, New Windsor, Md., and took his medical course at the University of Virginia, Charlotteville, from which he was graduated June 30, 1870. After an internship of one year at the Bay View Hospital, Baltimore, he entered the U. S. Navy as an assistant surgeon, Nov. 1, 1871; was made passed assistant surgeon, Nov. 1, 1874, and resigned from the Navy, June 30, 1875. On the following day he was appointed first lieutenant and assistant surgeon, U. S. Army; was made captain and assistant surgeon five years later; was promoted to major and surgeon June 6, 1894; to lieutenant colonel Aug. 6, 1903, and to colonel, Medical Corps, April 23, 1908. After serving at several posts, he was detailed to duty at the U. S. Military Academy, West Point, in July, 1894, and continued in this work until May, 1898, when he was ordered to equip and take charge of the U. S. A. Hospital Ship *Relief* and in this capacity serving in Cuba and Porto Rico and the United States until October. At the termination of the Spanish-American War, Dr Torney was ordered to duty as instructor in hygiene at the Army School, Fort Leavenworth, Kan. In August, 1889, he was placed in command of the Army and Navy General Hospital, Hot Springs, Ark., and continued this duty until November, 1902, when he was sent to the Philippine Islands where he was placed in command of the First Reserve Hospital, Manila, from December, 1902, until July, 1903. On his return from the Philippine Islands in 1903 he was appointed chief surgeon of the Department of California and after four months was placed in command of the General Hospital, Presidio of San Francisco, and served in this capacity from March, 1904, until December, 1908. During this time the San Francisco earthquake and fire occurred and he was placed in charge of the sanitary work of the stricken city, and made there for himself a brilliant record as an administrative officer and a sanitarian. From November, 1907, to December, 1908, he was again chief surgeon of the Department of California and on Jan. 14, 1909, he was appointed surgeon general of the Army on the retirement of Brigadier General Robert M. O'Reilly. General Torney was a Fellow of the American Medical Association, and president of the Association of Military Surgeons of the United States at its Milwaukee meeting in 1911. He was also chairman of the War Relief Committee of the American National Red Cross. In every position in which General Torney was placed, he showed marked efficiency. He was much esteemed by the members of the Medical Corps of the Army; which loses in his death an administrative officer of great merit and a sanitarian of high rank.

GEORGE H. TORNEY, 1850-1913

Peter McKittrick, M.D. Rush Medical College, 1889; a Fellow of the American Medical Association; of Eau Claire, Wis.; died in the Sacred Heart Hospital in that city, December 17, from disease of the throat, aged 47.

Alexander Erskine, M.D. New York University, New York City, 1858; a member of the Tennessee State Medical Association; surgeon of the Fifteenth and Second Tennessee Infantry, C. S. A., during the Civil War; emeritus professor of obstetrics and pediatrics in Memphis Hospital Medical College; dean of that institution from 1868 to 1873; for several terms president of the Memphis and Shelby County Medical Society; died at his home in Memphis, December 13, from senile debility, aged 81.

Edmund L. B. Godfrey, M.D. Jefferson Medical College, 1875; a Fellow of the American Medical Association; for many years a member of the staff of the Cooper Hospital, Camden; at one time president of the Medical Society of New Jersey and secretary of the State Board of Medical Examiners; a surgeon in the National Guard for twenty-nine years, retiring as colonel and assistant surgeon-general; died at his home in South Pasadena, Cal., December 18, from heart disease, aged 63.

Mary M. Arnett, M.D. Hahnemann Medical College, Chicago, 1896; of Boulder. Colo.; who started on a trip around the world a year ago by way of the west, died suddenly in Edinburgh, Scotland, October 12. from heart disease, aged 59.

Alvaro E. Mossman, M.D. Bellevue Hospital Medical College, 1881; a member of the staff of the Haywood Memorial Hospital, Gardner, Mass.; a member of the Massachusetts Medical Society; was found dead in bed, December 19, aged 56.

Frederick Normal Swift, M.D. Long Island College Hospital, 1896; Baltimore Medical College, 1899; a member of the Medical Society of the State of New York; died at his home in Beekmantown, December 5, aged 52.

James Dorr Clyde, M D. College of Physicians and Surgeons, New York City, 1867; a veteran of the Civil War; formerly a druggist; died at his home in Cherry Valley, N. Y., December 4, aged 70.

Faulkner A. Short, M.D. University of Toronto, Ont., 1902; a member of the Oregon State Medical Association; died at his home in Portland, December 11, from heart disease, aged 39.

Reuben H. Chase, M.D. Detroit Homeopathic Medical College, 1872; formerly of Denver, Colo.; died at his home in Long Beach, Cal., December 10, aged 76.

Henry Banga, M.D. University of Basel, Switzerland, 1875; a Fellow of the American Medical Association; well known gynecologist of Chicago; professor of gynecology in the Chicago Policlinic; dean of the attending staff of Michael Reese Hospital; died while attending a patient in Chicago, December 24, from cerebral hemorrhage, aged 66.

Hugh Cary, M.D. University of Michigan, Ann Arbor, 1894; a member of the Michigan State Medical Society; formerly president of the village of Delray, a suburb of Detroit; a member of the Board of Education and school inspector of Detroit; at one time health officer; died at his home, December 14, from arteriosclerosis, aged 61.

Thomas M. Crosby (license, Mississippi, 1888); a member of the Mississippi State Medical Association and vice-president of the Newton-Neshoba-Winston County Medical Association; of Neshoba; died in Newton, Miss., December 16, from carcinoma of the liver, aged 52.

Richard G P. Dieffenbach, M D College of Physicians and Surgeons, New York City, 1884; a Fellow of the American Medical Association, treasurer of, and visiting surgeon to the Newark (N J) German Hospital, physician to the Home for the Friendless and Hebrew Orphan Asylum, vice president of the West Side Trust Company, Newark, and a member of the city council in 1884 and 1885; died at his home in Newark, December 17, from cerebral hemorrhage, aged 61

Frank Edward Agnew, M D. College of Physicians and Surgeons, New York City, 1885, a member of the Medical Society of New Jersey, a member of the staff of the Paterson General Hospital, attending physician of the Isolation Hospital, formerly city physician of Paterson, died at his home, December 17, from pneumonia, aged 49 The Paterson Board of Health and Passaic County Medical Society, at a meeting, December 17, adopted resolutions of regret and sympathy

Benjamin Frank Wagenseller, M D. Pennsylvania Medical College, Gettysburg, 1861, assistant surgeon of the 139th and surgeon of the 158th Pennsylvania Volunteer Infantry during the Civil War, a member of the Medical Society of the State of Pennsylvania and once president of the Northumberland and Snyder County Medical societies, local surgeon of the Philadelphia and Erie and Northern Central railroads, died at his home in Selin's Grove, December 20, aged 5

Adaline Marshall Watson, M D Woman's Medical College of Pennsylvania, Philadelphia, 1898, a Fellow of the American Medical Association, formerly president of the Woman's Medical Society of Pittsburgh, physician to the Margaret Morrison School of the Carnegie Institute of Technology Pittsburgh, a member of the staff of Columbia Hospital, Wilkinsburg, died in a hospital in Pittsburgh, December 17, aged 47

William Edgar Rice, M D George Washington University, Washington, D C, 1878, formerly a Fellow of the American Medical Association, Association of Military Surgeons of the United States and American Academy of Medicine, acting assistant surgeon U S P H Service, city physician of Bath, Me, from 1880 to 1885, died at his home, December 17, from heart disease, aged 61

John Domingo Fernandez, M D. Medical College of Virginia, Richmond, 1870, a Fellow of the American Medical Association, one of the organizers and for many years secretary and treasurer of the Florida Medical Association, secretary and treasurer of the Regular Board of Medical Examiners, died at his home in Jacksonville, December 15, from cerebral hemorrhage, aged 65

William C Bartram, M D. College of Physicians and Surgeons, New York City, 1904, a Fellow of the American Medical Association and a member of the staff of St Luke's Hospital, Newburgh, N Y died at his home in that city, December 17, from septicemia, following an operation wound, aged 34

John Hunt Crosby, M D University of Michigan, Ann Arbor, 1904, a Fellow of the American Medical Association, a well known practitioner of Plainwell, Mich, and a member of the local school board, died in the Bronson Hospital, Kalamazoo, December 17, two days after an operation for appendicitis, aged 36

Gary Hosmer Wood, M D Long Island College Hospital, Brooklyn, N Y, 1877, a member of the Medical Society of the State of New York, for five years a member of the general assembly and chairman of the committee on public health, died at his home in Antwerp, December 18, aged 59

Thomas Chalmers Christy, M D Bellevue Hospital Medical College, 1874, a member of the Medical Society of the State of Pennsylvania, a veteran of the Civil War, a practitioner of Pittsburgh until 1900 and thereafter a resident of Pasadena, Cal, died at his home in Pasadena, December 18, aged 67

Henry Lorenz Obetz, M D Homeopathic Hospital College, Cleveland, 1874, a Fellow of the American Medical Association, professor of clinical surgery in Detroit Homeopathic College, a member of the staff of Grace and St Mary's hospitals, died at his home in Detroit, December 20, aged 62

Francis LeBau Parker, M D. Medical College of the State of South Carolina, Charleston, 1858, formerly professor of anatomy and dean of the faculty of his alma mater, a surgeon in the Confederate service throughout the Civil War, died at his home in Charleston, December 15, aged 77

Robert A. Smith, M D. Physio Medical Institute, Cincinnati, 1870 a member of the Indiana State Medical Association, of New Castle, Ind, a veteran of the Civil War, died at St Vincent's Hospital, Indianapolis, December 15, two days after an operation on the bladder, aged 70

Richard Wisdon Allen, M D. Bellevue Hospital Medical College, 1872, a member of the State Medical Association of Texas, emeritus professor of diseases of the chest in Southwestern University, Dallas, for many years a railway surgeon, died at the home of his daughter in Independence, Mo, December 21, aged 68

Harry W. Taggart, M D Marion Sims Medical College, St Louis, 1896, a member of the Medical Society of the State of California, once superintendent of the San Joaquin County Hospital, of San Mateo, died in St Luke's Hospital, San Francisco, December 14, aged 46

Eugene Woodworth McCord, M D. Jefferson Medical College, 1890, for several years a member of the staff of the St Paul City Hospital, a member of the Minnesota State Medical Association, died at his home in St Paul, December 21, from cerebral hemorrhage, aged 59

Byrne E Robinson, M D. McGill University, Montreal, 1892; a Fellow of the American Medical Association, died at his home in Arnold, Neb, December 19, from nephritis, aged 48

William Colby Cooper, M D Eclectic Medical Institute, Cincinnati, 1867, for many years editor of the *Medical Gleaner;* died at his home in Cleves, Ohio, December 7, aged 78

Henry T. Duffield, M D. Washington University, St Louis, 1882, of Pittsfield, Ill, a Fellow of the American Medical Association, died in St Louis, December 15, aged 60

James Walter Allen, M D. Fort Worth, Texas University, 1898, of Newark, Tex, died in Fort Worth, December 8, after a surgical operation on the kidney, aged 38

Herbert M Clapp, M D University of Vermont Burlington, 1890, of Stratford, Conn, died in Florida, December 12, *aged 50*

Marriages

Allard Memminger, M D, to Miss Margaret Aloysius Coleman, both of Charleston, S C, at Newport, R I, December 9

William Forrest Youmans, M D, Squaw Shoals, Ala, to Miss Mary Lenora Williams, of Tuscaloosa, Ala, December 23

Ulysses Schuyler Colfax Busch, M D, Jennings, Mich, to Miss Edith Bloomquist of Cadillac, Mich, December 17

Colin G Robertson, M D, Sandusky, Mich, to Miss Florence S Detwiler of Brown City, Mich, December 17

Lewis Mines Allen, M D, Winchester, Va, to Miss Dorothy Gilpin of Baltimore, at Winchester, December 10

Henry G Penner, M D, Plymouth, Neb, to Miss Anna Zimmerman of Beatrice, Neb, December 4

Frank B Sanford, M D, Morley, N Y, to Miss Lillian Lawrence of Lisbon, N Y, December 9

Lew Paul Murphy, M D, Pasco, Wash, to Miss Harriet Friend of Sheridan, Wyo, recently

Alexis Carrel, M D, New York City, to Mme. de la Marie of Paris, France, December 26

John William Jones, M D, to Miss Curie Sieber, both of Berkeley, Cal, December 11

John Edward Clark M D, to Miss Evelyn Brogley, both of Streator, Ill, December 10

Clifford Rush Eskey, M D, to Miss Mae Bogert of Chicago, January 1

Physiologic Test of Drugs—Van der Wielen incidentally give an interesting account of the practical steps taken in Holland to employ digitalis of a definite strength Sufficient of the plant is grown at Amsterdam for the use of pharmacists in Holland, to whom it is sent *out labeled with the* result of both physiologic and chemical tests The medical men are supplied with the particulars of each year's crop, so that they can order whichever supply they may judge to be best suited for the case The discussion went on for some time, but eventually the section agreed unanimously to the following resolution The Second Section of the Eleventh International Congress of Pharmacy, having heard the report of MM Ginzberg and Meulenhoff, expresses the opinion that the *principle of determining the* therapeutic value of certain drugs by physiologic methods should be adopted whenever the chemical test does not give sufficient indications —The *Chemist and Druggist.*

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

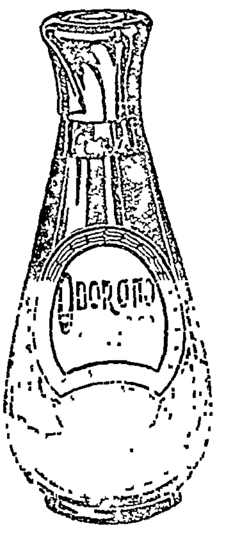
ODOR-O-NO

A Dangerous "Perspiration Preventive"

A number of inquiries have come to The Journal regarding the composition of a widely advertised toilet preparation called "Odor-o-no." It is put on the market by the Odorono Company, Cincinnati, Ohio, which has for its president A. D. Murphey, for its secretary and treasurer, E. G. Murphey, and for its advertising and sales manager, F. J. Rottmueller.

"Odor-o-no" is sold as the "anti-dress-shield toilet water." Some of the claims made for this product are:

"Keeps the armpits free, dry and natural."
"Eliminates excessive perspiration."
"A perfect antiseptic and a superior deodorant."
"Guaranteed by the manufacturer to be absolutely harmless."
"It restores the skin secretions to normal."



Odor-o-no has been extensively advertised and evidently has a large sale. More than a year ago the Indiana State Board of Health warned the public against the use of this preparation. Mr. William D. McAbee, drug chemist of the Department of Food and Drugs, declared that "Odor-o-no" was a solution of aluminum chlorid which, when applied to the skin, would be decomposed and act as a violent irritant. Several instances were reported to have been brought to the attention of the state board in which "Odor-o-no" had caused ulcers.

In the latter part of September of this year an inquiry was received about "Odor-o-no" and the report of the Indiana state chemists was sent to our correspondent. This information apparently did not satisfy the correspondent, who complained that it was a year old and that he understood "the manufacturer of 'Odor-o-no' had made some changes in his formula." In view of this and the numerous other inquiries received, it was thought worth while to analyze "Odor-o-no" in the Association's laboratory. The chemist's report follows:

CHEMIST'S REPORT

"Two original, sealed bottles of 'Odor-o-no,' manufactured by the Odorono Company, Cincinnati, Ohio, were purchased by the Chemical Laboratory of the American Medical Association, from a local supply house, and subjected to a chemical examination. The bottles contained a rose-scented red liquid, which was acid to litmus paper. The specific gravity of the liquid was 1.16. The following constituents were demonstrated to be present: aluminum, sodium, chlorid (traces of sulphate) and a red dye.

"The quantitative relations were found to be as follows:

Aluminum (Al)	3.38 per cent.
Chlorid (Cl)	14.12 per cent.
Sodium (Na)	0.17 per cent.
Water and perfume (by difference)	82.33 per cent.
	100.00 per cent.

"Inasmuch as the solution was acid, the difference between the chlorid found and that calculated from the percentage of aluminum and sodium present, is attributed to free hydrochloric acid. Calculation shows 100 c.c. of the solution to be composed essentially as follows:

Aluminum chlorid ($AlCl_3.6H_2O$)	38.8 gm.
Hydrogen chlorid (HCl)	0.86 gm.
Sodium chlorid (NaCl)	0.48 gm.
Water and aromatics to make	100 c.c.

"A third sealed bottle was purchased Nov. 15, 1913, directly from the manufacturers. Aluminum chlorid was found to be present as the essential constituent in this specimen also, and a trace of sulphate was found. For practical purposes 'Odor-o-no' may be looked on as a 33 per cent. solution of aluminum chlorid (hydrous)."

SUMMARY

Evidently the rumor that the manufacturers of "Odor-o-no" had changed their formula is without foundation. The stuff is essentially what it was more than a year ago, a solution of aluminum chlorid. When "Odor-o-no" is placed on the skin, the perspiration decomposes it into aluminum hydroxid and hydrochloric (muriatic) acid. The acid of course will attack the skin, while the aluminum hydroxid (or oxid) is apt to clog the pores. The preparation is both fraudulent and dangerous.

THE KANSAS VIEWPOINT

"We hope the physicians of Kansas will not lose sight of the fact that no drug is advertised in the pages of their state journal that has not been approved by the Council on Pharmacy and Chemistry of the American Medical Association. No doubt there are many remedies used by the profession of the state which have not thus been approved, but it should not be so. The Council has no exactions that cannot be met by any honest firm. The Council is the only body which stands as a protector of the medical profession against misrepresentation and fraud on the part of unscrupulous manufacturing chemists. It is, as it were, like a clearing house, which sets the seal of approval on preparations that are offered to the medical profession.

"If a doctor goes to a town where he is not known and asks for credit, he is promptly met with a request for recommendations. His own word is not accepted as evidence of his responsibility. If he wishes to borrow money from a bank, the bank officials may be morally certain that the obligation will be canceled according to promise, but before the money is handed over your name must be appended to a note and perhaps, too, that of a friend to indorse it. No one takes exception to this fair and business-like way of conducting business.

"Likewise, we should demand that preparations which we are asked to use shall have the endorsement of the Council, and there is no good and sufficient reason why the manufacturers should offer the slightest objection to the requirement, in fact the endorsement of the Council should be sought rather than shunned."—H. B. C. in the *Journal of the Kansas State Medical Society*.

AN EXAMPLE OF U. S. PATENT OFFICE WISDOM

As an illustration of the kinds of patents that are issued by the U. S. Patent Office, we give in full a patent granted Dec. 9, 1913. The number is 1,081,069, Serial No. 665,142.

To whom it may concern:

Be it known that I, Alois Vaquerat, *doctor of medicine*, a citizen of Switzerland, residing at Lausanne, Canton of Vaud, in the Confederation of Switzerland, have invented certain new and useful Improvements in Medicinal Compositions, of which the following is a specification.

The present invention relates to a composition which is intended to be used internally and which confers to the organisms immunity against the following microbial infectious illnesses: *diphtheria, pneumonia, typhus, scarlet fever, influenza, septic infections, cerebral spinal meningitis, syphilis, pest, cholera and tuberculosis, it is also effective in another kind of disease, viz.: goiter.* [Italics not in original.—Ed.]

This remedial composition or substance does not contain any substances strange to the organism. Therefore the innocuity of the remedy is perfect. The principal of these substances is creatinin, creatinin used alone in the quantity of from 0.05 gram to 0.10 gram is a sure remedy against diphtheria. For all other diseases already mentioned, pneumonia, typhus, scarlet fever, influenza, septic infections, cerebral spinal meningitis, syphilis, pest, cholera, tuberculosis and goiter, it is preferable to mix with the creatinin two other substances, allantoin and guanidin. The creatinin is the controlling agent, but the two others mentioned impart to the creatinin *more efficacy*.

This remedial composition is intended to be taken internally in the form of sirup, pastils, pills or the like. It may for example advantageously be of the following composition: 0.20 part by weight of chemically prepared creatinin, 0.01 part by weight of guanidin, 0.10 part by weight of allantoin, 100.00 part by weight of water. This solution is mixed with a small quantity of an excipient substance such as for instance acid pulp of tamarind or a few drops of lemon juice or an organic acid, for example malic or tartaric or citric or succinic acid and the like. Sugar may also be added. The acids are employed for acidulating the paste of the pastils or other forms of the remedy in order to prevent the creatinin from being converted into creatin which has no efficacy at all.

It is to be understood that I do not confine myself to the above mentioned proportions, although those given I have found from practice to give the best results.

I claim as my invention:

1. A medicinal composition for internal use containing chemically prepared creatinin, guanidin and allantoin.

2. A medicinal composition for internal use comprising the following ingredients: 0.20 part by weight of creatinin, 0.01 part by weight of guanidin, 0.10 part by weight of allantoin, 100.00 parts by weight of water, with which is mixed an excipient substance.

In testimony whereof I have affixed my signature in presence of two witnesses. ALOIS VIQUERAT

Witnesses:
Rod De Wurstemberger,
G. Imer.

It appears that the inventor is dead, and that his estate took out the patent. Since this great benefactor should have been, by the use of his preparation, immune to practically all diseases, he must have died of senility, although this seems hardly to have been the case. Assuredly granting patents on such claims ought to be sufficient to show the need of a change in the methods of granting patents—at least of the methods governing the issuance of patents for medicinal products.

DECENCY PAYS

The Phoenix Republican Proves It

"We can't afford to do it!" Such is the plea, or excuse, of the average newspaper carrying fraudulent medical advertising when asked to *drop* this source of revenue. Public opinion is shaping itself so rapidly that the time is not far off when newspapers will find that they cannot afford to *carry* fraudulent advertising. It has been repeatedly shown that where publications have thrown out the fraudulent medical advertisements from their pages they have gained not only in self-respect and in the respect of their readers, but in advertising receipts. More and more is it becoming evident that the decent advertiser favors the paper that caters to decent advertising.

This as a preface to an editorial in the Phoenix (Ariz.) *Republican*, Dec. 14, 1913. It is entitled "New Standard of Newspaper Decency." Here it is:

"When the *Republican*, not quite a year ago, determined to eliminate patent medicine and other objectionable advertising from its columns it expected no other reward than a satisfied conscience. The management was aware that it was about to cut off a source of considerable revenue, and it did not figure that another would in consequence succeed it. The striking out of this kind of advertising was one way of improving the *Republican*, and newspapers cannot be improved without expense or financial sacrifice.

"Patent medicine advertisements are offensive to a large number of, though not all, intelligent readers. A certain class of such advertisements, those relating to secret diseases and others relating to appliances and mixtures which suggest in themselves only an immoral use, are offensive to all decent readers.

"The *Republican* believed that as the bearer of such messages from advertisers it would not be true to its mission as a family or home newspaper, and it therefore determined that its advertising pages should be purged. Though its action was independent and, in any event, would have been taken, though it stood alone, the *Republican* enlisted in a movement for newspaper reform which is spreading all over the country. A large number of the better known newspapers are now throwing out patent medicine and other offensive advertising, but it is a matter of pride to the *Republican* that it is making a more thorough clean-up than any other secular newspaper of which we have any knowledge.

"The *Republican* has found other reward than the approval of its own conscience. The eliminated advertising has been followed by a considerably increased volume of decent advertising. The patent medicine people used to be tyrannical when the papers were clamoring for their business. They not only insisted on the best positions, but designated the kind of matter that should appear next to their advertisements, and even proscribed other kinds of advertising on the same page. When the *Republican* began throwing out patent medicine advertisements the space thus cleared was taken by legitimate foreign advertising. *The patent medicine people are now* clamoring to get back into the *Republican* on any terms on 'any old' page. They are willing to leave the matter of position entirely to the foreman.

"The approval of the people of Phoenix and the state has been given this cleaning up of the advertising columns in a much more substantial manner than we expected. As a matter of fact, we had expected *no increase* of subscriptions in consequence. Yet within the period in which most of the advertising contracts expired and when they were dropped, there has been a steady and rapid increase in the *Republican's* volume of circulation as was shown in the published statement of yesterday and to-day. The *Republican* is naturally proud of the class of subscribers who have been attracted by this particular improvement.

"The time, we believe, is near when a patent medicine advertisement will be found in no newspaper which prefers any claim to decency. Newspaper times have changed and are changing."

When will the medical profession demand of its own publications the same regard for decency and truthfulness in advertising that public opinion is requiring of lay publications!

A CONTRAST

Our readers will be interested in comparing the attitude of two drug manufacturers toward the recent scientific investigation of natural and synthetic salicylates by the Council on Pharmacy and Chemistry. The Merrill Company meets the facts which were unfavorable to their claims by the familiar weapons of innuendo and abuse. The following excerpts are taken from the *Therapeutic Digest*, the house organ of Wm. S. Merrill Chemical Company for November, 1913.

> After the publication of a number of articles in THE JOURNAL by laboratory workers more or less closely associated with the Council on Pharmacy and Chemistry, *a final statement has been issued in* the usual form and pomp of authority characteristic of that body, that there is no difference in the action of salicylates and that the statements that differences exist are unfounded.
>
> No objection can be made to the members of the Council holding whatever opinion or reaching conclusions that may seem to them wise in the light of their limited experience. The Council is however never satisfied with an expression of its own views, but must force them onto others whose experience may contradict them and it denies expression of the opposing view in the pages of THE JOURNAL.
>
> For the blind followers of the Council the question of the salicylates seems to have been finally settled by this medicopapal bull, but for the independent and self-respecting physician no question can be settled by the autocratic edict of a self-constituted authority.
>
> The recent dictum of the Council as to the salicylates is said to be based on clinical experience as well as laboratory experiments, but the experiences themselves are kept profoundly secret.

The falsity of the last statement is shown by the fact explained in Dr. Hewlett's paper in THE JOURNAL, Aug. 2, 1913, p. 320, that the summaries of these cases have been published in reprints of Dr. Hewlett's article and are available to any one on receipt of a two-cent stamp.

In contrast to the foregoing, it is gratifying to read the following fair reference to the results of the Council investigation in *Lloyd Brothers' Bulletin*:

> We have always asserted that the superiority of natural salicylic acid, if it be superior to the artificial, depends on the presence or absence of by-products peculiar to each. The Committee on Therapeutic Research of the Council on Pharmacy and Chemistry, through Dr. W. A. Puckner, secretary, has decided as follows (see JOURNAL A. M. A., Sept. 20, 1913, p. 979):
>
> 1. Contrary to certain statements in the older literature there is no difference in the toxic dose for animals between 'natural' sodium salicylate, the most highly purified synthetic, and the cheapest commercial sodium salicylate on the market.
>
> 2. The evidence for the claimed clinical differences, as found in medical literature, is extremely unsatisfactory and inconclusive.
>
> 3. No significant chemical impurities are present in commercial synthetic salicylate.
>
> 4. No difference can be detected clinically, either in the therapeutic or toxic effects, if the comparison is made under conditions which strictly exclude personal bias.
>
> *The Council therefore concludes* that there is no difference in the actions of 'natural' and synthetic salicylates, and that statements that differences exist are unfounded."

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

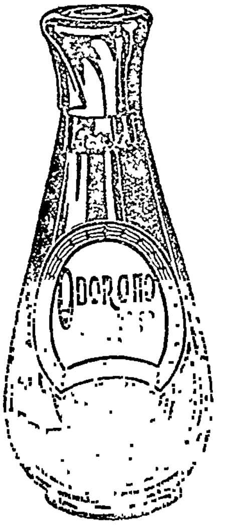
ODOR-O-NO

A Dangerous "Perspiration Preventive"

A number of inquiries have come to THE JOURNAL regarding the composition of a widely advertised toilet preparation called "Odor-o-no" It is put on the market by the Odorono Company, Cincinnati, Ohio, which has for its president, A. D. Murphey, for its secretary and treasurer, E. G. Murphey, and for its advertising and sales manager, F. J. Rottmueller.

"Odor o no" is sold as the "anti dress shield toilet water." Some of the claims made for this product are:

"Keeps the armpits free, dry and natural"
"Eliminates excessive perspiration . ."
"A perfect antiseptic and a superior deodorant"
"Guaranteed by the manufacturer to be absolutely harmless"
"It restores the skin secretions to normal"



Odor o-no has been extensively advertised and evidently has a large sale More than a year ago the Indiana State Board of Health warned the public against the use of this preparation. Mr. William D. McAbee, drug chemist of the Department of Food and Drugs, declared that "Odor o no" was a solution of aluminum chlorid which, when applied to the skin, would be decomposed and act as a violent irritant. Several instances were reported to have been brought to the attention of the state board in which "Odor o no" had caused ulcers.

In the latter part of September of this year an inquiry was received about "Odor-o-no" and the report of the Indiana state chemists was sent to our correspondent. This information apparently did not satisfy the correspondent, who complained that it was a year old and that he understood "the manufacturer of 'Odor-o-no' had made some changes in his formula." In view of this and the numerous other inquiries received, it was thought worth while to analyze "Odor-o-no" in the Association's laboratory. The chemist's report follows:

CHEMIST'S REPORT

"Two original, sealed bottles of 'Odor-o no,' manufactured by the Odorono Company, Cincinnati, Ohio, were purchased by the Chemical Laboratory of the American Medical Association, from a local supply house, and subjected to a chemical examination. The bottles contained a rose scented, red liquid, which was acid to litmus paper. The specific gravity of the liquid was 1.16. The following constituents were demonstrated to be present: aluminum, sodium, chlorid (traces of sulphate) and a red dye.

"The quantitative relations were found to be as follows:

Aluminum (Al)	3 38	per cent
Chlorid (Cl)	14.12	per cent
Sodium (Na)	0 17	per cent
Water and perfume (by difference)	82 33	per cent.
	100 00	per cent

"Inasmuch as the solution was acid, the difference between the chlorid found and that calculated from the percentage of aluminum and sodium present, is attributed to free hydrochloric acid. Calculation shows 100 c.c. of the solution to be composed essentially as follows:

Aluminum chlorid ($AlCl_3,6H_2O$)	38 8	gm
Hydrogen chlorid (HCl)	0 86	gm.
Sodium chlorid (NaCl)	0 48	gm.
Water and aromatics to make	100	c c.

"A third sealed bottle was purchased Nov. 15, 1913, directly from the manufacturers. Aluminum chlorid was found to be present as the essential constituent in this specimen also, and a trace of sulphate was found. For practical purposes 'Odor-o-no' may be looked on as a 33 per cent. solution of aluminum chlorid (hydrous.)"

SUMMARY

Evidently the rumor that the manufacturers of "Odor-o-no" had changed their formula is without foundation. The stuff is essentially what it was more than a year ago, a solution of aluminum chlorid. When "Odor-o-no" is placed on the skin, the perspiration decomposes it into aluminum hydroxid and hydrochloric (muriatic) acid. The acid of course will attack the skin, while the aluminum hydroxid (or oxid) is apt to clog the pores The preparation is both fraudulent and dangerous.

THE KANSAS VIEWPOINT

"We hope the physicians of Kansas will not lose sight of the fact that no drug is advertised in the pages of their state journal that has not been approved by the Council on Pharmacy and Chemistry of the *American Medical Association*. No doubt there are many remedies used by the profession of the state which have not thus been approved, but it should not be so. The Council has no exactions that cannot be met by any honest firm. The Council is the only body which stands as a protector of the medical profession against misrepresentation and fraud on the part of unscrupulous manufacturing chemists. It is, as it were, like a clearing house, which sets the seal of approval on preparations that are offered to the medical profession.

"If a doctor goes to a town where he is not known and asks for credit, he is promptly met with a request for recommendations. His own word is not accepted as evidence of his responsibility. If he wishes to borrow money from a bank, the bank officials may be morally certain that the obligation will be canceled according to promise, but before the money is handed over, your name must be appended to a note and perhaps, too, that of a friend to endorse it. No one takes exception to this fair and business-like way of conducting business.

"Likewise, we should demand that preparations which we are asked to use, shall have the endorsement of the Council, and there is no good and sufficient reason why the manufacturers should offer the slightest objection to the requirement; in fact, the endorsement of the Council should be sought rather than shunned"—H. B. C. in the *Journal of the Kansas State Medical Society*.

AN EXAMPLE OF U. S. PATENT OFFICE WISDOM

As an illustration of the kinds of patents that are issued by the U. S. Patent Office, we give in full a patent granted Dec. 9, 1913. The number is 1,081,069, Serial No. 665,142.

To whom it may concern:

Be it known that I, Alois Viquerat, *doctor of medicine*, a citizen of Switzerland, residing at Lausanne, Canton of Vaud, in the Confederation of Switzerland have invented certain new and Useful Improvements in Medicinal Compositions, of which the following is a specification

The present invention relates to a composition which is intended to be used internally and which confers to the organisms immunity against the following microbial infectious illnesses: *diphtheria, pneumonia, typhus, scarlet fever, influenza, septic infections, cerebral spinal meningitis, syphilis, pest, cholera and tuberculosis; it is also effective in another kind of disease, viz goiter* [Italics not in original —ED]

This remedial composition or substance does not contain any substances strange to the organism Therefore the innocuity of the remedy is perfect The principal of these substances is creatinin, creatinin used alone in the quantity of from 0 05 gram to 0 10 gram is a sure remedy against diphtheria For all other diseases already mentioned pneumonia, typhus, scarlet fever, influenza, septic infections, cerebral spinal meningitis, syphilis, pest, cholera, tuberculosis and goiter, it is preferable to mix with the creatinin two other substances, allantoin and guanidin The creatinin is the controlling agent but the two others mentioned impart to the creatinin *more efficacy*

This remedial composition is intended to be taken internally in the form of syrup, pastils, pills or the like. The falsity of the last statement is shown by the fact explained in Dr Hewlett's paper in The Journal, Aug 2, 1913, p 320, that the summaries of these cases have been published in reprints of Dr Hewlett's article and are available to any one on receipt of a two cent stamp

In contrast to the foregoing, it is gratifying to read the following fair reference to the results of the Council investigation in *Lloyd Brothers' Bulletin*

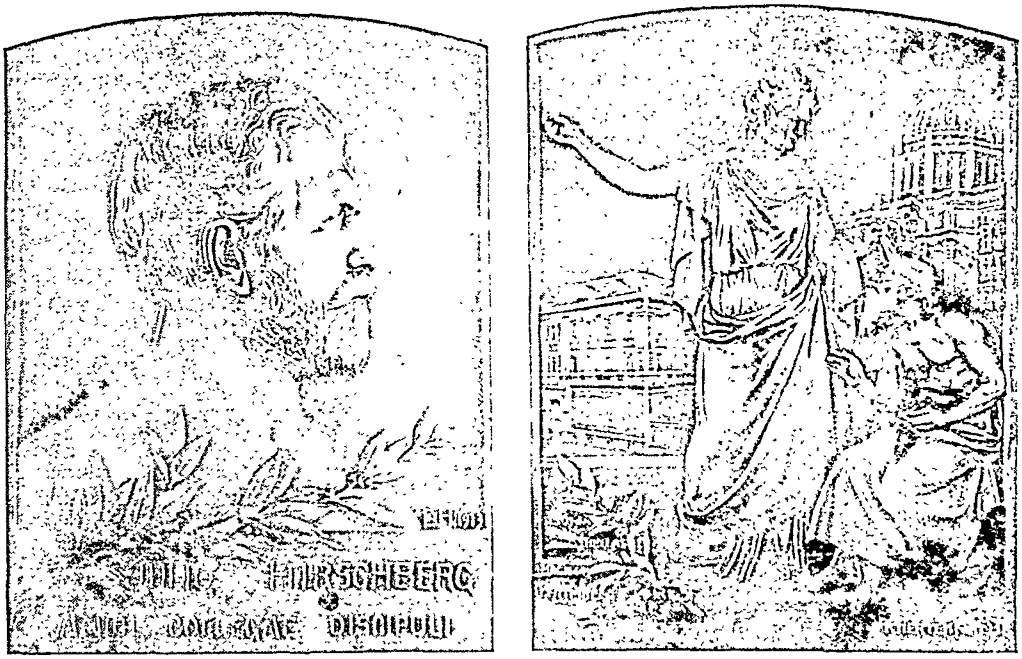
> We have always asserted that *the superiority of natural salicylic* acid if it be superior to the artificial, depends on the presence or absence of by products peculiar to each The Committee on Therapeutic Research of the Council on Pharmacy and Chemistry, through Dr W A Puckner, secretary, has decided as follows (see Journal, A M A Sept 20, 1913, p 979)
>
> '1 Contrary to certain statements in the older literature, there is no difference in the toxic dose for animals between 'natural' sodium salicylate the most highly purified synthetic, and the cheapest commercial sodium salicylate on the market
>
> 2 The evidence for the claimed clinical differences, as found in medical literature, is extremely unsatisfactory and inconclusive
>
> '3 No significant chemical impurities are present in commercial synthetic salicylate
>
> 4 No difference can be detected clinically, either in the therapeutic or toxic effects, if the comparison is made under conditions which strictly exclude personal bias
>
> 'The Council therefore concludes that there is no difference in the actions of 'natural and synthetic salicylates, and that statements that differences exist are unfounded"

Correspondence

A Well-Merited Honor to Julius Hirschberg of Berlin

To the Editor:—Julius Hirschberg was 70 years old. September 18. His friends, pupils and colleagues joined in celebrating the event by the publication of a selection from his medical writings from 1868 to 1912 in a stately volume of almost 900 pages, a volume splendidly arranged and most useful for reference and for study (Julius Hirschbergs ausgewählte Abhandlungen (1868-1912) zu seinem 70. Geburtstage, Ihm ueberreicht im Namen seiner Schüler von Oscar Fehr und Wilhelm Mühsam, Veit & Co., Leipsig, 1913).

On the evening of September 18 a banquet was arranged in Dr. Hirschberg's honor in Berlin, and on this occasion a medallion was presented to him. Among those who subscribed to this testimonial was the Section on Ophthalmology of the American Medical Association, of which Dr. Hirschberg has been an honorary member since 1905. The medallion (6 by 8 cm.) is a work of art and presents a striking likeness of Dr. Hirschberg. On the reverse is a beautiful design showing Ophthalmic Science raising the veil from the blind. On one side the royal palace at Berlin is seen in the distance, on the other the old eye clinic, which is familiar to so many American ophthalmologists. In the corner below are stacked up the more important works which Hirschberg has published.



Medallion to Julius Hirschberg: obverse and reverse.

It is gratifying to his friends that the American profession through the Section on Ophthalmology participated in showing honor to this veteran of ophthalmology.

Harry Friedenwald, M.D., Baltimore.

The Misuse of Scientific Articles by Proprietary Manufacturers

To the Editor:—Some years ago I read a paper before the Harlem Medical Association concerning "Conjunctivitis and Its Treatment." The Dios Chemical Company of St. Louis has made use of this article in advertising its product, "Palpebrine." While the company makes no statement to the effect that I indorse the preparation, it is evident that both physicians and laymen get the impression that my paper is in the nature of a testimonial of "Palpebrine."

The facts are, I do not use "Palpebrine," do not know its composition, and would not use it if I did know. To my mind such preparations are altogether unnecessary. I wrote to the Dios Chemical Company, protesting against this use of my paper and received word from it to the effect that no more pamphlet reprints of the paper would be sent out.

Frank Van Fleet, M.D., New York City.

Comment.—The misuse of scientific articles by proprietary manufacturers is not so common to-day as it used to be, but as Dr. Van Fleet's letter shows, the practice is evidently not entirely obsolete. If every physician whose name is used as an advertising asset by nostrum manufacturers would protest, this particular evil could be entirely abolished.

Activity of Parke, Davis' Detail Men

To the Editor:—A representative of Parke, Davis & Company, either of his own accord or in accordance with instructions, is making certain statements to the physicians of this district that are, it seems to me, worthy of consideration. He states that the Council is composed of a body of men who are, for purely personal reasons, hostile to P. D. & Co., and that they at one time said that they "would get P. D. & Co.," that P. D. & Co. had only recently prevented them from making a report on a sixteen-year-old sample of fluidextract of ergot, P. D. & Co.; that some time ago the Council had requested P. D. & Co. to submit an unstandardized sample of fluidextract of digitalis, U. S. P., for examination, but at the same time had permitted H. K. Mulford & Company to submit their standardized product not made in accordance with the U. S. P., and that a report published some time ago in The Journal was on different fluidextracts, and not U. S. P. extracts, and, finally, that P. D. & Co. were an immensely wealthy concern hiring the best experts that money could get; that they paid *no attention to the Council* and proposed to destroy it.

I am inclined to believe that this is a part of a well defined campaign of education (?) that is being carried on by the employees of P. D. & Co. wherever they may be, and that the attention of the profession should be called to it.

J. C. Stone, M.D., Wayland, Iowa.

The Quality of Drugs Sold to Dispensing Physicians

To the Editor:—The following letter, signed "Frank G. Ryan, President," has been sent to medical and pharmaceutical journals by Parke, Davis & Co.:

> "Will you do us the kindness to read pages 858 and 859, Journal of the A. M. A., September 13? Notice the slurring statement that our Fluid Extract Digitalis, U. S. P., is only 57.66 + per cent. potent.
>
> "A glance at the enclosed labels will show you that we market two fluid extracts of Digitalis—one, No. 597 (which was NOT tested by Puckner and Hatcher), F. E. Digitalis, P. D. & Co., which is PHYSIOLOGICALLY STANDARDIZED AND STRONGLY ALCOHOLIC; the other, No. 209, F. E. Digitalis, U. S. P., which is not *physiologically standardized. Observe the very explicit language* of the 'Note' at the foot of each label. Could anything be plainer or more definite?
>
> "In Dr. Puckner's tests he includes—doubtless for good and sufficient reasons of his own—our F. E. Digitalis, U. S. P., which we market only in deference to an existing demand; but the superior product which we standardize physiologically, and which we expressly recommend as more reliable and active than the official, he omits wholly from his comparison.

> "We contend that the official menstruum is not the one best fitted properly to extract the drug, that the fluid extract made by use of the official menstruum deteriorates rapidly, that this menstruum is inferior to the one we use for our F E Digitalis P D & Co, No 597, and that the U S P extract does not come up to our own standard as represented by the last mentioned product We do claim, however, that our F E Digitalis, U S P, is made from the best quality of drug in strict harmony with the official process We do not standardize it, we have never pretended to
>
> 'Furthermore, Dr Hatcher's 'cat method' of testing Fluid Extract Digitalis is rejected by Edmunds and Hale whose opinion of the 'cat method' is unquestionably shared to day by the vast majority of competent pharmacologists see Bulletin No 48 issued by the Hygienic Laboratory of the U S Public Health Service

One of Parke, Davis & Co's house organs, the *Bulletin of Pharmacy*, in its issue for December, 1913, p 486, contains a similar statement From this I quote

> 'W A Puckner the chemist of the American Medical Association, contributed a paper to a recent number of The Journal of the A M A, reporting among other things upon an examination made of various fluid extracts of digitalis upon the American market Parke Davis & Co was one of the four manufacturers involved and its fluid extract was said to be only 57 66 per cent of the standard We are informed by that house [the reader should bear in mind whose journal it is that is speaking], however, that for two reasons the findings of Dr Puckner are grossly unjust and fallaciously misleading"

According to reports which I have received, Parke, Davis & Co's detail men appear to have taken their stock arguments *from the matter quoted above* Parke, Davis & Co have thus attempted to create the impression that I discriminated against them in the paper referred to—"The Quality of Drugs Sold to Dispensing Physicians" Specifically, they complain that this examination included their regular U S P Fluid Extract of Digitalis, but did not include their own special, non official preparation

As Parke Davis & Co *seem to have misunderstood* the principles which governed the selection of the drugs for the examination, and as those who received their letter or listened to the firm's detail men may be misled, I wish to emphasize that the examinations reported on in my paper were in no way concerned with any firm's special or proprietary preparation, but dealt only with the regular, non proprietary, standard official drugs The principle on which the drugs were selected was to obtain those that the physician would have obtained had he written a prescription or sent to the source of his supplies Thus, in the case of fluidextract of digitalis the regular U S P title was used in ordering all of the brands, the order reading "Fluid Ext Digitalis, P D & Co" 'Fluid Ext Digitalis, Mulford," etc The examination of the fluidextracts of digitalis was an attempt to learn the quality of the market supply — the kind which the druggist, the physician and the patient would get I must say, however, that I was surprised to learn that Parke, Davis & Co should permit a preparation of digitalis to leave their establishment without biologic control I am all the more surprised in view of this statement, found in the firm's 1911 1912 catalog (the latest I have)

> All our Fluid Extracts are adjusted to a fixed alkaloidal or other standard, in cases where chemical reactions are not available, as with digitalis, aconite, ergot and a few others test is made on animals by methods which yield reliable data, not only of quality, but of degree of activity"

Evidently "All our Fluid Extracts" does not include fluid extract of digitalis, U S P.

Parke, Davis & Co contend that the official process is likely to produce a preparation which is weak and unstable, but the labels of Parke, Davis & Co and the Mulford Company products are practically identical so far as both declare the preparations to be "Fluid Extract Digitalis, U S P," to contain practically the same percentage of alcohol and to have been made at about the same time, the former Sept 3, 1912, and the latter Nov 23, 1912

In this connection it might be pertinent to call attention to another very important fact While Parke, Davis & Co are trying to evade responsibility by making it appear that the official fluidextract cannot be expected to be of good quality, at the same time the firm considers itself justified in saying that the U S P tincture may be prepared from it The following appears on the label of the Parke Davis & Co specimen examined

"Formula Tincture Digitalis U S P

Fld Ext Digitalis U S P	1 3/5	fluidounces
Diluted alcohol, sufficient to make .	16	fluidounces"

If the Parke Davis & Co fluidextract of digitalis, U S P, is not sufficiently active and reliable to represent the leaf perfectly—and the firm now admits this—it is extremely difficult to understand how they can justify their recommendation to pharmacists that the tincture be made in this way

The claim that Edmunds and Hale in Bulletin 48 of the *Hygienic Laboratory of the United States* Public Health Service had rejected Hatcher's "cat method" is unfair because the Hatcher method did not appear until about two years after the publication of this bulletin It is true that a cat method was reported on, but it was in no way so elaborate or so carefully worked out as the Hatcher method Although the Hatcher method has not been widely adopted it is generally conceded that by its use the comparative activity of digitalis preparations may be determined correctly

In conclusion let me say that this investigation of digitalis preparations was made in the interest of the public, the medical profession and scientific pharmacy and medicine, my paper was written, read before a section of the American Medical Association and published solely for the purpose of giving the medical profession the actual facts without fear of, or favor to, any firm, be it large or small

W A Puckner,
Director, Chemical Laboratory of the American
Medical Association

Hoffa's Statement as to Determining the Condition of Muscle

To the Editor —In the article on "The Treatment of Paralysis of Anterior Poliomyelitis" (The Journal, Dec 20, 1913, p 2219) there occurs a statement which is so very inaccurate that it seems to me to require correction After speaking of the difficulty of determining the power of the muscle by electrical examination Dr Frauenthal says, 'Hoffa always cut down on the muscle to determine its character" What Hoffa (*Orthopadische Chirurgie*, Ed 5, 1905, p 142) really said, in speaking of tendon transplantation, was as follows "If in spite of the closest examination, one is not prepared to decide whether the muscle in question is wholly or partly paralyzed, one may obtain information at the operation itself if one exposes not only the tendon but the belly of the muscle itself by a longer incision"

Robert W Lovett, M D, Boston

Stethophone and Stethoscope

To the Editor —Kindly permit me to say to Dr Joseph H Barach of Pittsburgh that "stethoscope" is really a genuine Greek word meaning, exactly, an instrument to *examine* the chest It appears that Dr Barach's Greek English dictionary is imperfect It is to be regretted that Dr Barach uses such hybrid terms as "auriscope" and "dictaphone"

A Rose, M D, New York

Quarantine and Individual Inconvenience —It is neither the province nor the intention of the Department of Health to give an individual or the public the preference over the other in quarantine matters This does not always seem so from the individual's point of view in cases of communicable diseases While quarantine may, *in some instances, result in* personal inconvenience and often in hardships, yet the safety of the community must be the first consideration The same measures which work an apparent hardship also serve as a protection This is a well established principle in public health administration and has been upheld by the courts The convenience of the few must be subject to the safety of the many —Buffalo *Sanitary Bull*

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

SALOMON-SAXL URINE-SULPHUR TEST FOR CANCER

To the Editor —Please publish in detail the Salomon-Saxl urine-sulphur test for cancer

O C BREITENBACH, M D, Frazee, Minn

ANSWER —For this reaction, dilute 150 c.c. of urine with 100 c.c. distilled water (albuminous urine must first be boiled, treated with a small quantity of acetic acid and carefully filtered); then add 150 c.c. Salkowsky's barium solution (a mixture of 2 parts barium hydroxid solution, saturated at room temperature, with 1 part barium chlorid solution saturated at room temperature). Filter and to the clear filtrate add more reagent to insure complete precipitation Then the ethereal sulphates are removed from the entire filtrate by adding 30 c.c. hydrochloric acid (specific gravity 1.12), transferring to a 500-c c flask, covering with a small funnel and *heated to boiling on an asbestos mat, with a small flame,* for an hour The flask is then covered with a beaker and allowed to stand on a water bath till the supernatant liquid is clear (requiring from four to twenty four hours). Now filter twice through a double "barium filter," small; wash the flask with sodium hydroxid solution and distilled water; boil again, using same precautions as above, and filter through a double "barium filter" (If there is still more precipitate formed, place the flask on the water bath again.) Now treat 200 c.c. of the filtrate with 3 c.c. strong hydrogen peroxid solution (perhydrol Merck) and boil fifteen minutes, covering again with the funnel, in the same flask. Now the liquid is poured into a sedimentation glass and then observed in from one-half to four hours In cases of carcinoma a decided sediment will be observed, while a normal urine may show a trace of such a sediment; as a rule normal urine does not show a sediment in four hours—but some time later a trace of ethereal sulphate not properly removed as above may show. The sediment obtained in case of carcinoma is usually some what colored, but this color can be removed by alcohol ether.

"HYDROCYANATE OF IRON—TILDEN"

To the Editor —Is it advisable to give "Hydrocyanate of Iron," prepared by the Tilden Company, St. Louis, in a case of epilepsy?

GEORGE F WAY, M D, Buffalo, Ill

ANSWER —It certainly is not advisable to give this substance if for no other reason than that it is a secret preparation. If we judged from the name, it would indicate that the preparation is a cyanid of iron, and a careful physician would hardly wish to give his patients any form of cyanids; but an examination of this nostrum by the Chemical Laboratory of the American Medical Association showed that it is essentially a mixture of approximately equal parts of talc and Prussian blue, containing traces of organic matter having the general properties of alkaloids Prussian blue is a remedy that has been used for epilepsy and found wanting; hence its use has been abandoned.

For further information see THE JOURNAL, June 19, 1909, p. 2008.

NOMINATORS AND ADJUDICATORS OF THE NOBEL PRIZE FUND

To the Editor:—Please give me the names and addresses of those who have charge of the Nobel prize awards

HARRY FEAGLES, M D, Morton, Wash

ANSWER —The president of the board of control administering the Nobel Prize Fund is A. F. C. Wachtmeister, Kungl Karolinska Medico Kirurgiska Institutet, Stockholm, Sweden.

Following are the prize adjudicators of the Nobel Prize Fund:

For physics and chemistry: Kungl. Svenska Vetenskapsakademien, Stockholm. The secretary of the commission is Knut W. Palmær, Kungl. Tekniska Högskolan, Stockholm.

For medicine: Kungl. Karolinska Medico-Kirurgiska Institutet, Stockholm. The president of the commission is K. A. H. Mörner, Stockholm.

For literature: Svenska Akademien, Stockholm. The secretary of the commission is E. W. Dahlgren, Stockholm.

For peace: The Norwegian Nobel committee.

Only certain persons are eligible to hand in names of candidates for the various prizes. The following includes those eligible to send in names for the prizes in medicine:

Members of the professional staff of the Karolinska Institutet.

Members of the medical class in the royal academy of science

Those persons who have received a Nobel prize in the medical section.

Members of the medical faculties at the Universities of Upsala, Lund, Christiania, Copenhagen and Helsingfors.

Members of at least six other medical faculties to be selected by the staff of the Karolinska Institutet in the way most appropriate for the just representation of the various countries and their respective seats of learning.

Scientists whom the said staff may see fit to select. The selections under Sections 5 and 6 shall be made within the first half of September, the initial proposal to emanate from the Nobel committee.

DETRIMENTAL EFFECTS OF ALBUMIN-MILK

To the Editor —Please refer me to any literature or reports of cases showing detrimental or fatal effects from the use of albumin-milk in acute intestinal disease in infants, following nutritional disturbances from low tolerance of sugars or fat.

P. M, Louisiana.

ANSWER.—Below are given a number of reports by different clinicians on their results with the use of albumin-milk. In nearly every instance the author reports the number of cases treated, the number of cures and the number of deaths:

Beck, Carl *Jahrb f Kinderh.*, 1912, lxxv, 315.
Grulee, C G Albumin-Milk in Infant-Feeding, *Am. Jour. Dis. Child*, September, 1911
Wiede *Therap Monatsh.*, 1911, xxv, 83.
Neff, F C Recent Experiences in the Artificial Feeding of One Hundred Infants, THE JOURNAL, Dec. 23, 1911, p 2068.
Morse, John Lovett The Use of Malt Sugar and High Percentage of Casein in Infant Feeding, *Am. Jour. Dis. Child*, November, 1911, p 315
Birk *Monatschr f Kinderh*, 1910, ix, 140.
Nothmann: *Jahrb. f Kinderh*, 1910, lxxii, 347.
Chapin, H D The Nutrition of the Feeble Infant, THE JOURNAL, Oct 22, 1910, p 1455
Braunmuller *Munchen. med. Wchnschr*, 1910, lvii, 2571.

AUTHORITIES ON TECHNIC OF COUNTING BACTERIA IN MILK

To the Editor —Please give the most approved technic of counting bacteria in milk P. H. M.

ANSWER.—The technic for these methods is too extensive to be reproduced in THE JOURNAL. The number of bacteria will differ according to the method which is adopted. We would suggest reference to the following authorities:

Hyg Lab Bull 56, U. S *P. H S*, p 437.
Savage, William G: Milk and Public Health, New York, the Macmillan Company, 1912, p. 177.
Standard Methods for the Bacterial Examination of Milk, by Committees of the Laboratory Section, American Public Health Association, reprinted from *Am Jour. Pub. Hyg*, August, 1910.

USE OF ACID SODIUM PHOSPHATE—VALUE OF QUININ IN COLON BACILLUS INFECTIONS

To the Editor:—1 Please discuss briefly the method of administration and dose of acid sodium phosphate when given to acidify the urine.

2 Is there any evidence that quinin sulphate given internally is of value in colon bacillus infections of the urinary tract and other parts of the body? R. G. D.

ANSWER —1. Acid sodium phosphate has been admitted to N. N. R., and its uses are described in that work. It is discussed in a Query and Minor Note, Aug. 3, 1912, p. 387.

2. So far as we can learn, there is no evidence that quinin sulphate is of value in colon bacillus infections.

TREATMENT OF GOITER WITH HIGH FREQUENCY CURRENT

To the Editor:—Has any success been attained in the treatment of simple goiters with the high-frequency current?

GEORGE S GILPIN, M D., Stoutsville, Mo

ANSWER —We can find no reference to such treatment in recent literature. A standard work on electrotherapy which was published in 1913 makes no mention of it.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, Jan. 13. Chairman, Dr. W. H. Sanders, Montgomery.

Colorado: State Capitol, Denver, January 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Illinois: The Coliseum Annex, Wabash Ave. and 16th St., Chicago, Jan. 14-16. Acting Sec., Amos Sawyer, Springfield.

Indiana: Room 56 State House, Indianapolis, Jan. 13-15. Sec., Dr. Wm. T. Gott, 56 State House, Indianapolis.

Iowa: The Capitol Bldg., Des Moines, January 6-8. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

Minnesota: State University, Minneapolis, January 6-9. Sec., Dr. Thos. S. McDavitt, 814 Lowry Bldg., St. Paul.

New Hampshire: State House, Concord, January 6-7. Regent, Mr. H. C. Morrison, State House, Concord.

New Mexico: Santa Fe, Jan. 12. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: Jan. 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Albany.

North Dakota: Grand Forks, January 6. Sec., Dr. G. M. Williamson, Grand Forks.

Oklahoma: Oklahoma City, Jan. 13. Sec., Dr. John W. Duke, Guthrie, Okla.

Oregon: Portland, January 6-8. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.

South Dakota: Capitol Bldg., Pierre, Jan. 13. Sec., Dr. Park B. Jenkins, Waubay.

Vermont: Montpelier, Jan. 13-15. Sec., Dr. W. Scott Nay, Underhill.

Washington: Spokane, January 6-12. Sec., Dr. F. P. Witter, Traders' Block, Spokane.

Wisconsin: Madison, Jan. 13. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

Pennsylvania's June Examination—A Correction

A recent communication from the office of the Bureau of Medical Education and Licensure of Pennsylvania indicates that, in the report of the June examination published in The Journal of Nov. 15, 1913, through an error in copying, a failure was charged against Howard University, Medical Department. The candidate who failed was a graduate of the Harvard Medical School.

Michigan October Report

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 14-16, 1913. The number of subjects examined in was 13; the total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 12, of whom 9 passed and 1 failed. Two candidates were conditioned. Seventeen candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Boston University School of Medicine	(1899)	70.8*
Harvard Medical School	(1911)	80.3
University of Michigan, Dept. of Med. and Surg.	(1902)	81.6
Jefferson Medical College	(1913)	83
University of Pittsburgh	(1913)	79
University of Virginia	(1911)	89.8
University of Toronto	(1911)	76.9, 83.7
University Sv. Vladimira, Russia	(1897)	84.6

*Allowance of 10 per cent for 14 years of practice.

FAILED

College	Year Grad.
Michigan College of Medicine and Surgery	(1904)*
Syracuse University College of Medicine	(1892)+*
University of Toronto	(1913)+*

* No grade given.
+*Conditioned in Chemistry.

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of Colorado	(1912)	Colorado
George Washington University	(1906)	Maryland
Northwestern University	(1910) Indiana, (1911)	Illinois

ANATOMY

1. Give the composition of bone. 2. Describe the radius and name bones with which it articulates. 3. To what class of joints does the ankle belong and what parts enter into its formation? 4. Name the muscles of mastication. 5. Give origin and distribu-

tion of superior, middle and inferior hemorrhoidal arteries. 6. Describe the stomach, giving nerve- and blood-supply. 7. Give the number and names of the lobes and ducts of the liver. 8. Give the contents of Scarpa's triangle. 9. Give the origin, course and distribution of eighth nerve. 10. Name the parts severed in amputation about middle of forearm.

PHYSIOLOGY

1. Give the functions of the (a) cerebrum, (b) cerebellum, (c) liver, (d) spleen. 2. Name the five nerve centers located in the lumbar enlargement of the spinal cord. 3. Name the five ductless glands, and give the functions of each. 4. Name the physical properties of normal urine. 5. What is aphasia? Give the different forms and causes of each. 6. How is heat produced in the body? 7. What is the normal ratio of heart pulsation to respiration? 8. Give the source of the white blood-corpuscles and their function. 9. Describe the functions and secretions of the stomach. 10. What nerve centers regulate body temperature?

CHEMISTRY

1. What is oxygen and how prepared? 2. What is water and how may river water be purified? 3. Define analysis and synthesis. 4. What is the principal solid constituent of urine? 5. What is a carbohydrate? 6. Give two tests for sugar in urine, giving details of one you prefer. 7. What is oleic acid? 8. What is vinegar and with what is it most often contaminated as found in the market? 9. What are proteids and from what are they derived? 10. What are ptomains?

PATHOLOGY

1. Define leukocytosis and give its two varieties. 2. What does leukocytosis with a predominance of polymorphonuclear leukocytes indicate? 3. What are the apparent differences in the throat lesions of diphtheria and follicular tonsillitis? 4. Mention some of the pathological lesions that are sometimes the sequelae of diphtheria. 5. Differentiate a chancre and a chancroid. 6. What pathological lesions are productive of icterus? 7. What abnormal products may be found in the urine as a result of interstitial nephritis and chronic parenchymatous nephritis? 8. By examining the fluid removed by a lumbar puncture, how may we distinguish between tubercular and other forms of meningitis? Without making a bacteriological examination, what microscopical findings would cause you to suspect tubercle bacillus? 9. Name some of the various crystals found in abnormal urine and state their significance. 10. Mention six diseases which may result in enlargement of the lymphatic glands.

BACTERIOLOGY

1. Define bacteria, state how they are recognized. 2. What is essential to the life of bacteria? 3. How do we determine if a certain organism is or is not pathogenic? 4. Define toxins, antitoxins and ptomains. 5. What class of bacteria produce rapid-spreading inflammation, and what class produce localized inflammation? 6. Define opsonins and describe the theory of phagocytosis. 7. How would you do a Widal reaction? 8. Name two methods of staining blood-specimens for malarial plasmodium; also detail method of examining fresh specimens of blood for malarial plasmodium. 9. Detail method *of producing and staining specimens of Spirochaeta pallida*. 10. Name the chief morphologic characteristics of the organisms producing the following diseases: diphtheria, tetanus, anthrax, gonorrhea and cerebrospinal meningitis.

THERAPEUTICS

1. Explain the difference between empirical and rational therapeutics. 2. How do the various diuretics promote the secretion of urine? 3. What is the method of action of disinfectants? 4. Explain the action of the following on the heart: digitalis, nitroglycerin and strychnin. 5. Give the therapeutics of hexamethylenamin (urotropin). 6. Give directions for preparing normal saline solution, and give indications for use. 7. Give the physiological action of opium. Give treatment of opium poison. 8. Give the therapeutic action of the arsenical compounds in common use. 9. Explain the therapeutic action of diphtheria antitoxin. Give dosage and mention untoward symptoms. 10. What therapeutic agents would you use in the treatment of typhoid fever, and give indications for same.

MATERIA MEDICA

1. Give rule for computing dose for children. State drugs that are an exception to rule, mentioning those that are well tolerated, and those that should be given cautiously. 2. Define alkaloid, glucoside, and neutral principle. Give example of each. 3. Give dose and physiological effect of the following: cocain, strychnin, atropin, pilocarpin and physostigmin. 4. Name five vasodilators and five vasoconstrictors, giving dose of each. 5. How do emetics produce emesis? Name five, giving dose of each. 6. Name the chlorids of mercury, giving general properties and methods of use. 7. Give composition and dose of the following: Fowler's solution, Donovan's solution, Dover's powder, Basham's mixture, and Vallet's mass. 8. What are hypnotics? Name five, giving dose of each. 9. How is anti-meningitis serum prepared? Give dose, method and frequency of each: iodin, salicylic acid, guaiacol, caffeine, and sulphona.

OBSTETRICS

1. Give the physical signs of pregnancy by the following classifications: (1) uterine, (2) vaginal, (3) abdominal, (4) mammary, (5) fetal, (6) reflex, (7) due to pressure and congestion, (8) cutaneous, (9) subjective, (10) Give also Heger's and Braxton Hicks' sign. 2. Define position and presentation, and give diagnostic points of vertex, left occipito anterior position, and breech presentation. 3. State in your own way how you would conduct a normal labor. Let this include your preparation, also the preparation of the patient. 4. Give the mechanism of labor in left occipito anterior position. Also give mechanism of labor in right occipito posterior. 5. Give cause and treatment of puerperal eclampsia. Also give danger signals of eclampsia. 6. Give cause and treatment of post-partum hemorrhage. 7. Give indications for the use of forceps and describe how you would apply in a case of left occipito anterior *position.* 8. Give treatment of puerperal infection. 9. Give causes of sudden death in the puerperum. 10. Give treatment of ophthalmia neonatorum.

GYNECOLOGY

1. Name the more frequent injuries to the mother in childbirth. State how they should be treated. 2. Give symptoms, diagnosis, prognosis and treatment of Neisser infection of the vagina. 3. What are the most frequent causes of pelvic cellulitis? 4. Describe operation for (a) cystocele, and (b) rectocele. 5. Describe the fol*lowing positions: Sims', Trendelenburg's, Fowler's* and *Edebohls'*, and state one or more operative procedures that may be facilitated by their employment. 6. At what period in a woman's life is uterine cancer most frequent, and what symptoms would lead you to suspect same and call for investigation? 7. Describe operation for ventral suspension in retrodisplacement of the uterus, and state what class of patients you would use the method with. 8. Describe Emmett's operation in detail for perineal repair. 9. Give chief points of differentiation between ascites and ovarian cyst. 10. Give causes, classification and treatment of tubal pregnancy.

SURGERY

1. Define infection. How does infection occur? What is specific infection? Give an example. 2. What nerve may become involved, and what paralysis may follow in fracture of the upper third of the humerus? 3. Give the causes and symptoms of a subphrenic abscess. 4. What are the symptoms of floating kidney? Give indications and technic of operation for its correction. 5. Define enterocele, epiplocele. Describe operation for radical cure of umbilical hernia, name tissues that are brought together. 6. Through what channels is carcinoma and sarcoma disseminated? 7. Differentially diagnose chancre, chancroid and herpes progenitalis. 8. Give symptoms and treatment of fracture of the nasal bones. 9. Give symptoms and treatment of gunshot and stab wounds of the abdominal wall involving the intestines. Describe the suture you would use in closing wound of intestines. 10. What is empyema? Give etiology, pathology and symptoms. State usual results when not treated.

THEORY AND PRACTICE OF MEDICINE

1. Define scorbutus. (b) What lesions are always present in scorbutus? (c) Give etiology and treatment. 2. Name two varieties of icterus neonatorum. (b) Treatment of each variety. 3. Give etiology, symptoms and treatment of facial paralysis. 4. What is an aneurysm? (b) Give diagnosis of aneurysm of thoracic aorta. 5. How would you differentiate fever of pyemic origin from intermittent malarial fever? 6. How would you treat dermatitis combustionis? 7. How would you treat acute poliomyelitis? 8. How would you treat orchitis complicating parotitis? 9. Give etiology, symptoms and treatment of acute rhinitis. 10. Give causes and symptoms of ileo-colitis.

HYGIENE

1. Explain the meaning of predisposing and exciting causes of disease. 2. Name the most common (a) animal and (b) vegetable parasites which produce disease. 3. Define temperament, idiosyncrasy and diathesis. 4. What is meant by ventilation? Give the amount in centimeters of air taken into lungs in an adult with each regular respiration. 5. What is the best method and disposition for removal (a) of sewage, (b) of garbage? 6. Name the four essential alimentary principles in food. 7. What diseases are conveyed by milk? 8. Give the method of pasteurizing milk. 9. What hygienic precautions should be observed by a pregnant woman? 10. In a clinical analysis of water, if nitrites and nitrates are shown, should it be condemned for drinking purposes; if so, why?

Book Notices

Materia Medica: Pharmacology: Therapeutics: Prescription Writing for Students and Practitioners. By Walter A. Bastedo, Ph.G., M.D., Associate in Pharmacology at Columbia University. Cloth. Price, $3.50 net. Pp. 602, with illustrations, Philadelphia: W. B. Saunders Company, 1913.

The advance of pharmacology is so rapid that the so-called latest text-books frequently do not contain our latest knowledge in regard to the action of certain drugs. This fact gives an advantage to a new book on the subject seldom possessed by the older books, which, even when revised, are apt to retain statements of discarded views. The work by Bastedo has been well done and presents in moderate compass an up-to-date view of the subject of pharmacology so far as it influences modern therapeutics. The subject of digitalis is worked out with especial fulness. The book favors the rational use of a few remedies with a thorough knowledge of their action, which must characterize the simpler and more practical therapeutics of the future. The book closes with an excellent chapter on prescription writing in which enough of Latin grammar is given to insure correct form without burdening the student's memory with unnecessary technicalities. There are some good hints as to the calculation of dosage, etc.

While the work is thoroughly practical it recognizes the value of research, and some remedies are mentioned only to be condemned because their use is not justified by modern investigation. The hypophosphites are characterized as useless and the modern substitute, the glycerophosphates, present no satisfactory evidence that they increase the phosphorus in the nervous tissues. Lecithin is regarded as having scarcely any advantage over eggs and milk. The discussion of the more important articles, such as iron, iodids, alcohol, etc, is eminently satisfactory

We believe that the practitioner as well as the student will find this volume a very practical and reliable guide in the field of pharmacology

TREATMENT OF INTERNAL DISEASES FOR PHYSICIANS AND STUDENTS By Prof Norbert Ortner Edited with Additions by Nathaniel Bowditch Potter, M D, Assistant Professor of Clinical Medicine at Columbia University Translated by Frederic H Bartlett, M D, Instructor of Children's Diseases at Columbia University Second Edition Cloth Price $5 Pp 643 Philadelphia J B Lippincott 1913

A second English edition of the fifth German edition of Ortner's book seems necessary at this time, owing to the large number of changes in the last edition in German The chapter on children's diseases has been rewritten entirely by Professor Fronz of Vienna As an aid in the treatment of diseases, the book is a valuable one, and the names of the editor and translator of the English edition are sufficient guarantee of the care with which the work has been prepared In reviewing the first edition in 1908, we said "The number of synthetics recommended is larger than is desired and it is *to be feared that some preparations have found a place in* the book that may outlive their period of service in actual practice" Of great significance, therefore, is the following statement from the preface of the new edition: "The editor has endeavored to comply with the suggestions of the Council on Pharmacy and Chemistry of the American Medical Association and so has omitted those drugs recommended by the author which have not been sanctioned by this body" Such a spirit is commendable and encouraging

MODERN MEDICINE Its Theory and Practice in Original Contributions by American and Fore · Sir William Osler, Bart, M D F R S edicine in Oxford University, and Thomas · of Medicine in the Jefferson Medical College Philadelphia Volume I Bacterial Diseases, Diseases of Doubtful or Unknown Etiology, Non Bacterial Fungus Infections The Mycoses Second Edition Cloth Price $5 net Pp 1093, with illustrations Philadelphia Lea and Febiger, 1913

The popularity of the first edition of this important work is evidenced by the necessity of a new edition at the end of six years Still, the progress in medicine is so rapid that a text book needs revision at the end of such a period In the present case, the revision has been thorough and the present volume presents matured conclusions based on the most recent researches Certain topics were deemed of somewhat minor importance and liable to so little change that they have been omitted from the present edition, the reader being referred to the previous edition for their consideration The articles are written by specialists who have carefully revised the text, condensing in some parts, but giving special attention to diagnosis and treatment New sections have been written on a number of subjects It is promised that the succeeding volumes of the new edition will follow promptly It is hoped that the work thus revised will continue to fill its place as a standard in medical literature for the English speaking peoples

Treatment of Compound Fractures of the Jaw—How Question of Charges Should be Considered

(Cozine vs Moore (Ia), 141 N W R 424)

The Supreme Court of Iowa reverses a judgment for $800 rendered for the plaintiff for alleged malpractice, saying that, on the record as made, it thinks the defendant was entitled to the directed verdict for which he moved on the ground that the evidence failed to show any negligence or breach of professional duty on his part The plaintiff had been thrown under the wheels of his loaded wagon His observable injuries were a wound on the back of the head, a "mashed" cheek bone, and two compound fractures of his left lower jaw The defendant a physician four or five miles distant, was sent for When he came, he found the plaintiff lying on the ground at the place of the accident He extended immediate temporary relief and removed the patient to his home In the treatment of the plaintiff the most difficult problem was presented by the compound fractures of the jaw The flesh wounds of the compound fractures were in the mouth, and more or less dirt had been forced into the mouth and into contact with the wounds by the circumstances of the accident The segment of the jaw between the two fractures had been drawn out of position by the contraction of the muscles and had been drawn upward One of the problems confronting the defendant was to restore such segment to its place and to secure it in its proper position In order to do that, sufficient force had to be applied in some way to overcome the tendency of the contracting muscles An instrumentality was constructed called an interdental splint The defendant called to his assistance an experienced dentist A wax impression was first made of the plaintiff's jaw and teeth That impression was used as a model for the construction of the interdental splint, which was made from rubber or gutta percha on the form of the wax impression It was so placed over the teeth of the patient as to hold the broken segment in place with a view thereby to bring the fractured ends in apposition and to accomplish a union thereof Provision was made for the cleansing of the patient's mouth several times daily The splint was kept in the mouth of the patient for a period of five weeks It was very uncomfortable It interfered with the closing of the plaintiff's mouth and with expectoration and with swallowing There was more or less infection present The plaintiff's breath became offensive In the course of five weeks he became sick with pleurisy Another operation was performed by another surgeon for the removal of pus from the pleural cavity The splint was removed at the expiration of five weeks A union had not occurred, or at least was not complete The patient's general condition was very grave and the chances of recovery were against him No further surgical attention was given to the jaw In time the union resulted, and at the time of the trial the place of fracture was not readily discoverable by the expert witnesses The alignment, however, was more or less imperfect

It was the contention of the plaintiff that the use of the interdental splint was unwarranted and clearly negligent on the part of the defendant, and that another surgical method, known to the profession, should have been adopted by the defendant, which consisted in drilling several holes in the jaw and in each end of the broken segment and drawing and holding the parts together with the use of a silver wire This method also had its perils In case of infection there was danger of necrosis of the bone It increased somewhat the danger of infection because it was impossible to wholly eliminate infecting bacteria from the mouth

Whether the defendant departed from the standards of his profession in his treatment of the plaintiff was a question which from its very nature must be determined in the main on the expert testimony of other physicians The court thinks that the testimony as a whole clearly fell short of a showing of negligence or want of skill in the defendant in the use of the interdental splint The most that could be said was that the witnesses, if in charge of the case, might have adopted a different course That would be a difference of judgment only Indeed, it could hardly be said from the testimony that the plaintiff's medical witness would have adopted a different course All experts agree that every difficult case presents a zone wherein the best method becomes largely a question of judgment of the attending surgeon under all the apparent circumstances of such particular case That the appliance was painful or inconvenient, and that infection resulted, and that the plaintiff's life was in great peril, were all matters incident to the natural results of the original injury The best of surgical treatment might not be able to avoid them The emphasis of the plaintiff's case was laid on these circumstances Of themselves they were clearly insufficient to prove negligence of the defendant

Some testimony was introduced by the plaintiff relating to the defendant's charges for his services The amount all told was over $1,500, and the defendant obtained from the plaintiff a promissory note for the greater part thereof It was also shown that the defendant sold the note. Complaint was made of this testimony as being irrelevant and immaterial and calculated to prejudice the jury The court fails to discover in the record any legal reason for the introduction of this testimony. In the absence of a showing of items entering into the sum total, it would impress the jury, as it impressed the court, as an extraordinarily large bill and could not fail to create a hostile feeling against the defendant. The amount of the verdict rendered was rather suggestive that the real intent of the jury was to reduce the defendant's bill to a reasonable extent, rather than to compensate the plaintiff for damages suffered as a result of negligence. If the defendant charged the plaintiff an exorbitant bill and improperly obtained his note therefor, a direct issue of that kind should be made and a recovery sought on such ground. An opportunity would thus be afforded to the defendant to justify his charges if he could. If there was an obstacle in the way of such suit by reason of a valid settlement, the same obstacle should bar the interjection of such question into this case. If the obstacle was surmountable, let the issue be directly made.

Rules as to Liability for Services Rendered on Request of Parents and Other Third Persons

(McGuire vs Hughes (N Y), 101 N E R 460)

The Court of Appeals of New York affirms a judgment of the Appellate Division affirming a judgment of the Apellate Term of the Supreme Court affirming a judgment entered in favor of the defendant, dismissing the complaint in this action, brought to recover the reasonable value of services rendered by the plaintiff as a physician, at the request of the defendant, to the latter's daughter, a married woman living with her husband. The court says that the only question on this appeal was whether the defendant came under any obligation to the plaintiff. That turned on whether the law *would imply a promise on her part to compensate him.* If the court might assume the existence of a moral obligation, that would not determine that a legal, or enforceable, obligation existed.

The rule in the United States has generally been that a physician is entitled to recover for his services, if not under an express contract therefor, then under an implied agreement to pay as much as they are reasonably worth, differing in earlier times, from the rule at common law, which, in England before the passage of the medical act of 1858, in the absence of a special agreement, denied to the physician the right to sue for his professional services, the theory of any payment to him being that of an honorarium.

It should be taken as the rule of law, too well settled on authority to be now questioned, that a physician, in the absence of a special contract, may recover on an implied agreement to pay for his services their reasonable value, when they have been rendered at the request of the patient, or of a person who, in the eye of the law, is regarded as being under a legal obligation to provide such professional services for the patient; such as a husband, or the parent of a minor child.

But the general rule that, when a person requests of another the performance of services, which are performed, the law implies a promise by the former to pay their reasonable value, has no application in the case of a physician, rendering *professional services to a third person,* if the relation to the patient of the person, who requests them, be not such as imports the legal obligation to provide them.

In the present case, notwithstanding the anxiety, the importunity, and the prayers of the defendant, how was the legal obligation of the patient's husband shifted to, or assumed by, the defendant? According to the plaintiff's testimony, he refused to attend the patient until the husband had consented; which may be said to be a recognition, at least, of the marital relation, with its consequent responsibility, or liability. It certainly followed that, when the husband's consent was given an obligation arose on his part to pay the reasonable value of the services which the plaintiff might render As there was no express promise by the defendant to pay, the court cannot hold, on the facts disclosed by the plaintiff's evidence, that there was also an implied promise on her part.

It would be a simple matter, in cases in which the physician is called on to attend a person, at the instance of some one not standing in a responsible relation to the patient, to inform himself as to whom he shall look for his compensation.

Insufficient Complaint and Evidence in Malpractice Case—Treating for Blood-Poisoning Case Later Diagnosed as Osteomyelitis

(Osborn vs Carey (Idaho), 132 Pac. R. 967)

The Supreme Court of Idaho reverses a judgment giving the plaintiff $4,000 damages for alleged malpractice, and grants the defendant a new trial. The court says that the plaintiff was a boy about 12 years old. It was alleged in the complaint that on or about Nov. 14, 1911, he was afflicted with a disease of his right leg, for which the defendant was called to treat him, and that the defendant carelessly failed to make a proper examination of him, such as a physician of ordinary skill would have done, and pronounced the disease to be blood poisoning, when in fact it was a disease of the leg "at the right tibia," which disease and ailment has well-known and peculiar signs and symptoms which an ordinary physician would detect, and that the defendant continued negligently and unskilfully to treat him for blood poisoning until about March 10, 1912. This allegation was too uncertain in that it did not appear from the complaint what was the name or nature of the alleged disease, or what were the signs or symptoms of the disease, which it was alleged were well known and peculiar.

In this class of cases, in order to enable counsel properly to prepare a case for trial, it is usually necessary for them to make considerable study of the ailment or disease with which it is claimed a plaintiff was suffering, in order that they may properly defend their client. The danger to the defendant in such a case on a general allegation of a disease claimed to be a "well-known disease," without naming it or giving its signs and symptoms, is certainly increased in a malpractice action over the ordinary action, and it would seem only fair to the defendant that the plaintiff should be required to name the disease with which he was afflicted. The defendant could not know prior to the trial for a certainty with just what disease the plaintiff would claim he was afflicted. Had he known, he might have made a better defense.

The complaint was also uncertain in that it could not be determined from its allegations whether the plaintiff claimed negligence in the treatment of a disease correctly diagnosed, or whether he relied on the fact that it was the wrong treatment for osteomyelitis. The defendant ought to have been advised by the allegations of the complaint in regard to that matter. If the court should assume that the exact charge of negligence as to the treatment related only to the mistake of the disease, and that the defendant had wrongfully diagnosed it as "blood-poisoning," and treated the ailment on the wrong theory as to the nature of the disease, the defendant would not necessarily be liable, even though as to the nature of the disease, the defendant would not necessarily be liable, even though the treatment did not produce good results, for it must appear from the allegations of the complaint that the treatment was not proper from the standpoint of the consensus of opinion among physicians and surgeons of ordinary skill and learning in the profession in the locality wherein the defendant practiced. In other words, even though the ailment were osteomyelitis, even though the defendant treated it as blood-poisoning, still the nature of the disease might be such that in the opinion of physicians they should be treated alike, and, if such were so, the defendant would not be liable for using such treatment, even though it did not produce good results.

In this class of cases the allegations of the complaint ought to be sufficiently specific to inform the defendant of the facts that he must meet by his defense, and the complaint ought to allege specifically the things concerning which the negligence is charged and the name of the disease with which the plaintiff was afflicted, and that was so here, since it was alleged that it was a "well-known" disease It was alleged in effect in the complaint that the defendant, on account of carelessness and negligence, failed to discover the true disease with which the plaintiff was afflicted, and it certainly was only fair to the defendant, if the disease was well known and had a name, that the name of the disease be alleged

Again, it was incumbent on the plaintiff to produce competent evidence on the trial to warrant the jury in finding that he really had osteomyelitis at the time he was treated by the defendant There was evidence in the record to show that he had osteomyelitis thirty days after the defendant's last visit, but it was contended there was no evidence in the record to show that during the time the defendant treated the plaintiff he was afflicted with such disease The existence of the disease on March 12 would not prove of itself its existence thirty days prior thereto, and the expert witnesses based their testimony of the existence of the disease at the time the plaintiff was being treated by the defendant on a 'history of the case," which was not put in evidence It was contended by counsel for the plaintiff that this objection was one which went to the competency of the evidence, and that question should have been raised in the court below by appropriate objection to the evidence, when the missing facts and circumstances, if they were material, could have been supplied The objection, however, went to the weight of the evidence and as to its value as proof, and not to its incompetency If a case depends on the opinion of the expert, and the truth of the opinion depends on the existence of certain facts and such facts are not shown, the opinion can have no value or weight as proof

In order to recover in this case the plaintiff must establish the existence of osteomyelitis during the time he was under the care and treatment of the defendant, the amount of damages sustained, as well as other facts There was not sufficient evidence to show that the defendant carelessly and negligently treated said disease or that the disease with which the plaintiff was afflicted at the time he was treated by the defendant was not blood poisoning or septicemia

Society Proceedings

NEW YORK NEUROLOGICAL SOCIETY, AND SECTION ON NEUROLOGY AND PSYCHIATRY OF THE NEW YORK ACADEMY OF MEDICINE

Joint Meeting, held Nov 11, 1913

Dr Smith Ely Jelliffe and Dr I Strauss Presided

The Irregular Bony Formations of the Sella Turcica in Some Epileptics

Dr L Pierce Clark and Dr E W Caldwell Cranial asymmetries and osseous deformities in epileptics have long been the subject of intensive study by many able investigators Some young epileptics present a markedly thickened skull, but usually the thickness is increased after the twenty fifth year and becomes very marked after the fortieth year The calvarium of the epileptic is heavier than that of the normal person of the same age Dr G C Johnston of Pittsburgh, Pa, was the first to study these cases roentgenographically Three types of the pathologically deformed and enlarged sella have been distinguished and classified by Cushing One is associated with thickening of the clinoid processes and dorsum ephippii Here the enlargement is accompanied by thickening of the walls, but Cushing stated that this type was confined to the acromegalics and gigantics, he believed that the bony thickenings were merely a feature of the osseous tendency to overgrowth, which of course, threw no light on the condition shown in some epileptics

The circulatory disorders in epilepsy shown frequently in slow pulse, vasomotor stasis in the extremities, and an invariably low blood pressure when arteriosclerosis was not advanced, the tendency to obesity and a ravenous appetite might make one pause before excluding the possibility that there may be some association between epilepsy and a marked disturbance of the pituitary body, and that it might ultimately be found that pituitary disease may sometimes have more or less bearing on some types of epilepsy in some of its broader and more general manifestations

Little or no reference has been made to this condition of irregular bony formations of the sella turcica by those who have made a special study of the cranium, and its significance could only be conjectured Dr Johnston of Pittsburgh was the first to suggest that it might have some bearing on epilepsy

Newer Researches Concerning the Hypophysis

Dr Frederick Tilney The ontogenesis of the hypophysis demonstrates the necessity of revising the nomenclature applied to it, inasmuch as certain neural and glandular elements have not hitherto been recognized The study of the development in a number of vertebrate forms is the basis for the following classification of the several parts of the organ

1 The pars neuralis, consisting of (*a*) the eminentia saccularis of the tuber cinereum, (*b*) the infundibulum, (*c*) the infundibular process 2 The pars glandularis (epithelial), consisting of (*a*) the pars tuberalis (hitherto undescribed), (*b*) the pars infundibularis, (*c*) the pars distalis

Some Causes of Disappointment in Operations on Brain Tumor

Dr William G Spiller, Philadelphia Bruns said that about thirty out of 100 brain tumors were so situated that a radical operation might be advised, the localization was accurate, and the tumor in these cases was accessible He believed that we might expect surgical success in from 3 to 4 per cent of all brain tumors Tooth studied the records of 500 cases of brain tumor at the National Hospital obtained during the years 1902 to 1911, inclusive Of these, about half came to operation He thought that a high mortality was inevitable, but that it could be reduced by a judicial choice of cases and by selection of the operation best suited for individual cases The immediate dangers common to all growths, all situations and apparently all operations, were shock, collapse and respiratory and cardiac failure

Many causes of disappointment occur to any one familiar *with operations for brain tumor* The best known are incorrect diagnosis the infiltrating character, large size and inaccessible situation of the tumor, errors in technic and impaired general vitality Increase of intracranial pressure is the cause of many of the general symptoms occurring with brain tumor It is attributed directly to the tumor and varies with the size of the growth There is a condition resulting from tumor to which little attention has been paid, and which is as important, if not more so, than the size of the tumor itself namely, enlargement of the brain This hyperplasia is not directly proportional to the size of the tumor it might be moderate with a large tumor or sufficient to cause much enlargement of one cerebral hemisphere when the tumor is small The hyperplasia might be the result of irritation either from pressure or possibly from some substance elaborated by the tumor, and is caused by an overgrowth of neuroglia tissue This hyperplasia of the brain might occur with any variety of tumor It should not be confused with enlargement from glioma tissue, nor should it be confused with the acute brain swelling of Reichardt The sudden fatal termination that occurs in some cases of tumor is probably the result of this enlargement of the brain, and of interference, by the general increase of intracranial pressure, with the important functions of the medulla oblongata It might also be that hyperplasia of the brain is an important cause of impairment of mentality in some cases of brain tumor

DISCUSSION

Dr M Allen Starr I have seen a number of cases of brain tumor associated with a distinct hypertrophy of the corresponding hemisphere, but have never ascribed to this condition the explanation offered by Dr Spiller The form of hypertrophy that follows operation in some cases and fails to occur in others has often puzzled me. I could not understand why in some cases after an operation for brain tumor there should develop an enormous hernia cerebri, while in other cases it was entirely absent, and I did not believe that it was always an evidence of sepsis. The distortion of certain parts of the brain resulting from tumor is a well-recognized fact, and by causing pressure on or stretching the cranial nerves it might give rise to secondary symptoms and obscure the diagnosis.

A review of my last fifty cases of brain tumor showed that the diagnosis as to the location of the growth was possible in thirty; in the remaining twenty, its location could not be determined definitely. In twenty of the fifty cases an operation was urged, and in eighteen of these it was performed. In eleven of the eighteen the operation confirmed the diagnosis, and the tumor was removed; in two the tumor was found, but could not be removed on account of difficulties encountered in connection with the operation; in five nothing was found. The death-rate was 6 per cent

Dr. B. Sachs: Doubtless many have observed this hyperplastic enlargement of the hemisphere accompanying brain tumor, but gave no heed to it. At the recent International Medical Congress in London, Sir Victor Horsley made the statement that unless the diagnosis was made before the appearance of optic neuritis, which was generally regarded as such an important feature of the condition, it was almost too late to do the patient any good. This is rather an extreme view. In the recognition of this condition it is not an easy matter to forego the advantages that go with the presence of a pronounced optic neuritis. I can recall a number of instances in which the diagnosis, without the eye symptoms, would have been practically impossible. In a case that was recently under my observation there was no optic neuritis, but there was evidence of tumor involvement of the fifth nerve. In addition to this, there were marked cerebral symptoms and an operation was contemplated, but after three weeks' observation in the hospital and under simple hygienic treatment all the symptoms gradually disappeared, with the exception of the fifth nerve involvement, and the patient has been temporarily discharged. I still believe that we had to deal with a brain neoplasm, but the patient was so much better that the idea of an operation has been abandoned for the present, at least.

The high mortality accompanying operation for brain neoplasms might perhaps be lessened to some degree by a more careful manipulation of the brain. This and the rapid checking of hemorrhage are important factors in the reduction of the death rate after these operations.

Dr. Robert Abbe: I have practically come to the conclusion that decompression is the operation of choice, on account both of its comparative simplicity and the benefits that accrue from it. I recall several instances in which this procedure was followed by great prolongation of life, together with improvement in the eye symptoms. In one case in which no tumor was found, although that diagnosis had been made and was well founded, the patient survived a decompression operation for four or five years and has resumed work. In another case in which the sight had been entirely lost the decompression resulted in restoration to health, and the patient was alive three years after the operation, when she was lost sight of.

Dr. J. Ramsay Hunt: I am familiar with the enlargement of the convolutions and parts of the hemisphere in the neighborhood of brain tumors, and I have always regarded it as the result of stasis due to an interference with the circulation, near the growth, of the blood- and lymph-streams. A similar condition was observed in abscess formation of acute onset, and under those circumstances the term "hyperplasia" was certainly scarcely applicable. I should be inclined to attribute this swelling and enlargement to a chronic stasis and edema, and not to a true hypertrophy or hyperplasia of brain tissue. It is not surprising that in old cases, as a result of pressure and stasis, there should be some changes in the appearance and relation of the histologic elements; but in my experience there has been nothing in the microscopic picture of the swollen region that would have suggested the occurrence of hypertrophy and hyperplasia.

Dr. Charles A. Elsberg: I have noticed this asymmetry between the size of the two lobes in cases of brain neoplasm, and have ascribed it to an increase of the fluid content on the affected side. I do not understand whether or not Dr Spiller attributes the occurrence of hernia cerebri to this hyperplasia. In many cases of hernia cerebri, the protrusion could be reduced by elevation of the patient's head or by lumbar puncture or by aspiration of the ventricles or the corpus callosum, or by a combination of these methods. The degree of pressure varied. At times a large, tense hernia occurred without apparent explanation, while at other times the protrusion was almost collapsed, and if it was attributable to this condition of hyperplasia, it would be difficult to understand these marked differences in the pressure.

Within the past few years I have seen two cases of tumor in the left frontal region, both located in the cortex and of the endothelial type, in which the wrong side of the brain was exposed. In both of these cases there was no increase in pressure; on the contrary, there was a diminution to such a degree that it led to a subsequent opening of the skull on the opposite side, where the tumor was really located

---

AMERICAN ASSOCIATION FOR STUDY AND PREVENTION OF INFANT MORTALITY

Fourth Annual Meeting, held in Washington, D. C., Nov. 14-17, 1913

The President, Dr. L. Emmett Holt, New York, in the Chair.

Infant Mortality—Past and Present

Dr. L. Emmett Holt, New York: Infant mortality is one of the great social and economic problems of our day. No resources of the state need so much to be conserved as its children. On the physical, intellectual and moral strength of the children of to-day the future of the country depends. In all training and education physical considerations must come first. Unless the infants are saved there will be no children to educate. The early attitude of the state and of the family toward the child was purely utilitarian; it aimed to provide for the survival of the child whose life might be advantageous to the state, and to eliminate all others. Thus the exposure to death of the feeble and the deformed was done without any hesitation or compunction. There are those to-day who believe that the high infant mortality tends to improve the race by eliminating the unfit in a process of natural selection. This assumes that those who are feeble and delicate in infancy are to be classed among the unfit. In the majority of cases this is not true. In a high infant mortality it is the unfortunate and not the unfit that are eliminated. General interest in saving the lives of infants is only fifty years old, and it has been active and efficient for barely twenty years.

Most of the modern agencies employed for the reduction of infant mortality have arisen in France. The first was the crèche or day nursery established in 1844. This was followed by societies for the protection of infancy and the promotion of maternal nursing, and finally the introduction in 1892 of the infant consultation and the milk-depot. These are places at which the mother of the young infant reports regularly to have her child weighed and examined and where she is given advice regarding its care. The infant consultation and milk-depot, having been adopted all over the world, are probably the most important agents yet devised for reaching the ignorant mother and aiding her in saving her child. In Germany at present attendance at these consultations is encouraged by a payment of a bonus of from 1 to 4 marks weekly to increase the family income sufficiently to enable the mother to nurse her child. In France also similar payments are made.

Since 1900 a world-wide campaign for the reduction of infant mortality has been in operation. Its results are shown nowhere better than in New York City, where the problem presents peculiar difficulties owing to the heterogeneous character of the population, the dense overcrowding, equaled nowhere else in the world, and the hot summer climate. What has been accomplished may be seen by the following figures: In 1890, in New York City, the death-rate was 28.8 per cent. of living infants; in 1908 it was 13.8 per cent.; in 1912 only a little over 10 per cent.

Simple Milk-Dilution Feeding

Dr. Herman Schwarz, New York: I wish to make a plea for the use of ordinary milk, water and sugar feeding. I believe in top milks in some cases, but I should like to emphasize the fact that it is only fair to the mother and in many cases to the child to try first the ordinary milk dilutions with the addition of sugar calorically sufficient. In institutional and clinical cases it is important not to make the feeding of infants a terrifically difficult problem with the use of a great deal of mathematics and apparatus. The addition of lime-water and of barley, unless indicated, and the use of other sugars beside the ordinary granulated or milk-sugar are also to be deprecated. The indiscriminate use of the malted sugars and infant foods is in many instances unnecessary, adding to the trouble of making the food, to the expense and to the time consumed in preparing it. In other words, unless there is some indication one should try the ordinary dilutions of milk, water and sugar in the greater percentage of our institutional patients. I can report the results of the use of such simple dilutions for 3,600 children, followed up for the period of a year. Many of these children are breast-fed until the eighth, ninth or tenth month; some have had to have milk mixtures added to or replaced entirely, at a much earlier period. When the addition of cow's milk is indicated the ordinary dilution of milk, boiled water and granulated sugar was almost always used. Of 1,182 infants thus fed and observed for a year, the average weight at the end of the year was 19 pounds and 14 ounces. The greater number of infants (approximately 75 per cent.) were over 18 pounds, and this in a material whose care could not be controlled absolutely and whose resistance to diseases was so lowered that a great many illnesses kept the weight back. Most of these babies received additional nourishment in the milk mixtures before the ninth month.

DISCUSSION

Dr. Godfrey R. Pisek, New York: This paper indicates the tendency toward simplicity, but Dr. Schwarz has not emphasized one feature which makes the simplified dilution of water, milk and sugar successful to-day. If ten or fifteen years ago we had tried simple milk-and-water dilution we would not have had the good results we have to-day because we have good milk now in the majority of cases. We had good results with our top-milk mixtures because doctors insisted on good milk in order to secure the top milk. To-day we obtain good results with whole milk because it is bottled milk. In the milk stations of New York City one year we tried pasteurized milk at some stations and raw milk at others. At the end of the year there was not much difference. The milk was handled under the direction of the nurses in the homes. The next year a good raw milk was again used, and these simple modifications were efficacious and we had good results. Simple dilutions will answer the purpose of the normal child; but in special cases we must adapt the modifications to the child.

Dr. L. Emmett Holt, New York: The difficulty is to keep people reporting regularly, and attending to the dilutions of milk according to the growth and needs of the child.

Dr. Julius Levy, Newark, N. J.: This paper is of immense social value because the average mother can be taught this system of feeding at home. This saves an immense amount of work on the part of the doctors, the nurses and the philanthropists; but best of all, it puts into the home the educational value of teaching the mother how to handle the milk. An association does an immense amount of work if it spreads the propaganda of simple milk modification among the doctors as well as among the mothers. The idea of feeding a child scientifically has been associated with a very elaborate knowledge of calories and percentages. If we can let every one know that simple milk modification will meet the average case, we shall have accomplished a great end.

Dr. H. F. Helmholz, Chicago: A great deal can be accomplished by the use of simple methods, if they are used rightly. Dr. Holt advocated simple methods from the very beginning; but simple methods may not help out if we have an infant that has had all sorts of mixtures fed to it before it came into our care. In our work in cities where thousands of babies have to be fed, we must have some simple procedure that can be taught the mother, and the simpler the procedure, the greater the chance of success.

Teaching of Hygiene and Its Relation to the Prevention of Infant Mortality

Dr. I. A. Abt, Chicago: How can the medical profession yield more efficient service in the prevention of infant mortality? Are our undergraduate and postgraduate medical schools contributing their share in instructing students in infant hygiene? Are infant hospitals, medical societies and other institutions of instruction and learning contributing their share in the propaganda of prevention? It has seemed to me at times that our energy in this campaign of prevention has been somewhat misdirected. I cannot fail to recognize the far-reaching effects on the reduction of infant mortality from the infant-welfare stations and the efficient service rendered by physicians and nurses in educating mothers and saving infant life. Nor would I discredit the campaign of education which has extended into many homes and brought light and relief into many dark places. In some medical schools, students learn what little they know about the hygiene of infants from the teacher of obstetrics; in a few schools the subject is taught by the department of pediatrics. In most schools the subject is taught indifferently, if at all. Infant hygiene should be taught in the department of pediatrics, should be given by one who is not a mere tyro in the department of children's diseases. The instruction should be based on physiologic knowledge, also utilizing such facts in clinical pediatrics, bacteriology and pathology as pertain to the hygiene of infancy.

The course in infant hygiene should consider the care of the infant during the first days of life, and the necessity for external warmth. The prevention of infection in the new-born is a theme worthy of careful study. The technic of the bath, its temperature, the warmth of the room and all other facts concerning its application are as important from the physician's point of view as from that of midwife, nurse or mother. The treatment of the cord, the umbilical wound, the clothing, should be considered in detail because they are matters of vital importance, simple when understood, serious or frequently fatal when misunderstood. The hygiene of food and feeding, the physiology of foods, the advantages of breast-feeding are all considered in the larger text-books on pediatrics and are easily accessible to every student. Air and exercise, the bathing of older children, the training of children, prevention of infections, and countless subjects and questions will come up for consideration, and should be treated in the greatest detail, because, after all, if medical schools are educating men for general practice, these various problems in infant hygiene which require daily application among normal and sick children are of the most far-reaching importance. Adequate training of young physicians in infant hygiene would be one of the most powerful forces in combating infant disease and mortality. The children's hospital should be a Mecca to which practitioners should pilgrimage. Popular lectures should be delivered at these hospitals as well as at undergraduate and postgraduate schools. Addresses should be delivered by competent physicians before district and county medical societies, so that the general practitioner of medicine might come into possession of the latest and most accepted methods of pediatric practice and particularly those facts which pertain to the hygiene and prevention of disease among infants.

DISCUSSION

Dr. J. H. Mason Knox, Jr., Baltimore: Most of us who are engaged in milk-station work and in seeing many children of the working classes, realize that a large part of our work is made necessarily simple because of the absence of the things which Dr. Abt has advocated. Some of us look on this crusade as pointing to the time when this knowledge of the hygiene of infancy will be more general. This knowledge of the elements of infant hygiene should be a part of all teaching of older girls in high schools and colleges. It is a legitimate part of every course of normal education, and until it is made so, we must continue in the present unsatisfactory way, through propaganda by societies like this one, and by means of the very discouraging attempts on the part of doctors and nurses to tell mothers who are beyond the age when learning comes easily, what mistakes they have already made in the care and feeding of their children.

Dr. Helen C. Putnam, Providence, R. I.: The graduates from high schools and colleges are only a small fraction of all the girls in the country. This society stands consistently and strongly for educating in continuation schools the great mass of girls who have no education at all during adolescence. One of the greatest things we can do in this society toward the prevention of infant mortality is to have these continuation schools—voluntary or compulsory—establish in every city in the country classes for teaching girls who are past the elementary school education how to take care of their children.

Dr. S. Josephine Baker, New York: This work is being done largely throughout the country by health boards, or through private organizations where the public authorities have not taken it up systematically. In New York we have our "Little Mothers' League," of girls from 12 to 14 who are taught these elements of baby care by lectures. Last year we had 17,000 girls in our league, and the attendance is entirely voluntary. The boards of education should take this up as a part of the public school course, and I believe as people interested in the welfare of infants we should make it our business to conduct a campaign of education among the educators themselves. We can do nothing more important for the women of the future than to teach them how to keep alive and well the children they will bring into the world.

Miss Harriet L. Leete, Cleveland: Our girls are being taught by the school nurses in Cleveland. This work has been taken up by the Babies' Dispensary after school hours. Children like it very much. This year it will come under the direction of the Board of Education.

(To be continued)

ENGLEWOOD BRANCH OF THE CHICAGO MEDICAL SOCIETY

Regular Meeting, held Dec. 2, 1913

The President, Dr. J. H. Hess, in the Chair

Headaches

Dr. Robert B. Preble: Headache is an extremely common symptom, occurring in practically every pathologic condition, yet there is no uniformity of opinion or actual knowledge as to where the pain is experienced. The dura is certainly devoid of sensory nerves, so that it can be cut without exciting pain. As we approach the base of the skull, however, the dura becomes progressively more and more supplied with nerves, mostly derived from the fifth cranial nerve. The pia and arachnoid are almost devoid of nerves, except the sympathetic. The brain tissue itself seems to be quite insensitive to pain. Whereabouts in these structures one feels pain, we do not know, but the presumption is that the pain is experienced in the dura, and rarely arises in the sensory branches from the fifth cranial nerve.

Many attempts have been made to classify headaches, but none has been satisfactory. We can think of a variety of pathologic conditions in which a mechanical explanation seems necessary, for example, the headache due to increased intravenous pressure. The nerve fibers are directly irritated by the pressure. There are certain chemical bodies which will precipitate headache very easily, such as nitroglycerin, and here again is an instance of increase in the intracranial pressure, dilatation of the vessels and irritation of the nerves. That idea is, in part, correct, as shown by clinical observation, but a much larger dose of nitroglycerin is required to produce a headache in a person whose vessels are thickened or sclerotic than in one whose vessels are responsive. It may be that the nitroglycerin irritates these nerves directly, but this classification is not satisfactory because it does not explain why the action is selective and does not give rise to pain anywhere else, and why this nerve is selected.

The classification I shall use is that of Auerbach, who divides headaches into a first group which he calls essential headaches, a second in which the headache is the result of diseases within the cranial cavity, and a third group in which the headache occurs in all sorts of conditions, remote from the skull.

The tendency is always to look on headaches in a superficial sort of way, and this is a serious mistake. Even though it is true that the great bulk do not amount to anything, nevertheless, every case of headache must be regarded as a problem of importance until it is certain that the headache is not the beginning of some serious illness. The history and the physical examination should be gone into with great care.

Among the cases of essential headache are those curious clinical pictures which we call migraine, thought by many to be the most common type of headache. In spite of the characteristic picture which many of these cases of migraine present, and in spite of the temptation which is so strong to dismiss them as mere migraine, one should not be too ready to do so, and particularly to dismiss as a case of migraine one which, no matter how typical the description, does not give a definite and clean cut history of heredity. A person may develop a migraine without a family history, but the number of such instances is very small. Furthermore one should not be too ready to accept a diagnosis of migraine which comes on late in life. Migraine almost invariably begins relatively early in life. So when a person comes with the complaint of migraine beginning at 40 or 50, one should be particularly careful in the examination. While such a conditon is possible, it is exceptional.

Another form of headache for which there is no satisfactory explanation is the headache of the neurotic person. When any normal person becomes tired out, overworked—particularly mentally—or is under a strain of any sort, headache is apt to develop, and a night's rest cures it. In neurasthenics headache becomes a common and troublesome phenomenon, and may be the only one of which the patient complains; but, in these cases, if the patient is intelligent, he will tell you that the headache is not comparable to what everybody understands by the term 'headache." The sensation is different. It may be painful—even excruciatingly so—but these patients will usually say that the headache is different from that caused by an acute intoxication of any sort. It is often described as an uncomfortable sensation between the scalp and the skull. There are sometimes localized areas of pain, pain which comes on under certain circumstances, and so on. Those people are usually readily recognized by any experienced practitioner as neurasthenics, but the same rule holds here, as always with neurasthenics: no matter how obviously they may be neurasthenics, the neurasthenia should not be accepted as an explanation of any given phenomenon until every possible organic explanation has been excluded, it is so easy for us to do the neurasthenic an injustice.

Another form of headache included in this group of essential headaches is the type, which I myself have never seen, called by the Germans indurative headaches—rheumatic headaches, conditions associated with nodules along the attachment of the muscles to the skull, and sometimes running down the muscles into the neck. Some of the German authorities say that this is the most common type of headache which is not due to any remote cause.

Then come the headaches which we associate in our minds with intracranial processes, with diseases of the meninges and diseases of the brain itself, particularly neoplasms of the brain. It is by no means universal for headache to develop in cases of this sort. I remember a patient who was convalescent from a pneumonia, and was to be discharged from the hospital in the afternoon of the day when he suddenly became unconscious and died in the course of a few hours. Necropsy showed that he had a most extensive purulent meningitis of the vertex, and yet it had caused no symptoms to attract attention He could not have suffered any particular headache, because he had gone about uncomplaining So it is quite possible for one to have extensive exudate processes in the brain which do not give rise to any symptoms

Brain tumor can reach a very considerable degree of size without giving rise to pain Whenever headache comes on with relative acuteness it should excite suspicion of the possibility of brain tumor, particularly if it is accompanied by the peculiar vomiting which is seen so often with brain tumor, a vomiting unassociated with nausea This is not always true, but nearly always the case

Of the affections of the meninges which give rise to headache, the most common one is meningitis Usually the diagnosis is not difficult—by lumbar puncture Then, there are the various infections, any one of which may present itself as a headache, although, as a matter of fact, there are not many in which the headache is a particularly prominent phenomenon In typhoid it is often the most striking feature, all the other *phenomena being entirely submerged in the headache,* which is so intense and prolonged that it is with difficulty that one can be convinced that it is not a graver process This extremely severe headache may be localized anywhere—it may be frontal, occipital or generalized If, in addition to the headache, one has some evidence of meningeal irritation, retraction of the head, a Kernig, possibly a little papillitis, the temptation is strong to make a diagnosis of meningitis, even though the typhoid is recognized A combination of the two occurs sometimes, but not often If a complicating meningitis is suspected, a lumbar puncture is easily made The only other common infection prone to give rise to intense headache is influenza In pneumonia the headache is rarely a complaint of moment, which is also true of the other common ordinary infections

In syphilis the headache is by no means an uncommon phenomenon, and in cases in which the syphilis does not manifest itself clearly it may be a source of great confusion The headache of syphilis is worse at night than in the daytime A Wassermann should be made, this will soon clear up the diagnosis

The question of the relation of malaria to headache in this part of the country does not often arise because of the infrequency with which we encounter malarial affections, but in regions where malaria is common that question frequently comes up Our diagnostic resources are such as to enable us to clear up the diagnosis, although the periodicity which is often noted in malarial headache will carry with it the suspicion of malarial cause

There is another form of headache, that which comes with nephritis, particularly in its slowly developing, insidious, diffuse or interstitial form Headache will be the first phenomenon that attracts the attention of the patient Always when a person in the latter portion of life complains of headache recurring, and that person in earlier years was free from such headaches, the possibility of nephritis should automatically occur If thorough examination is made the nephritis will not be overlooked In addition to the forms of headache referred to, there are also many cases in which the explanation can be worked out by careful study and elimination

Relation of the Nose and Accessory Sinuses to Headaches

Dr G Henry Mundt Severe pain in the *forehead,* particularly if it be unilateral, should arouse suspicion of an acute affection of the frontal or ethmoid sinus Pain in the upper jaw, especially if there be tenderness on pressure, should cause one to look for an acute antrum Headaches of nasal origin are peculiar The nose is ordinarily the last place to look for the cause of a headache Lack of ventilation in the nose and sinuses is accountable for more headaches than lack of drainage The latter causes pain in acute suppuration, but is of less importance in chronic conditions The pain is not always in the region of the sinus involved Chronic headaches for which everything has been tried without affording relief are usually nasal headaches

Grunwald gives the following conditions as causing headache (1) increase of mucosa, with irritation of the nerves, (2) direct contact of swollen mucosa, (3) negative pressure in the sinuses, (4) stasis following operation of the drainage passages, (5) ulceration of the mucosa with involvement of the nerves, (6) reabsorption of toxins from within the sinus, (7) any condition which causes acute congestion of the cranial circulation, and (8) disturbances of the blood and lymph circulation at the base of the skull In my experience, direct contact with a swollen mucosa has been a very frequent cause of headache I have found the middle and *occasionally* the inferior turbinal in contact with the septum Negative pressure in the sinuses has been the cause of many headaches The sinus is normally filled with air In these cases it is sealed, usually because the patient goes into a hot, stuffy room, which causes the mucous membrane at the opening of the sinus to swell Some of the air in the sinus is absorbed by the blood circulating there, and there is congestion in the mucous lining of the septum, causing a dull, heavy ache This variety of headache has been appropriately called vacuum headache I have found it more amenable to non surgical treatment that any other

Ulceration of the mucosa with involvement of the nerves is the principal cause of the headache which we find associated with atrophic rhinitis, but reabsorption of toxins from within the sinus is probably partially responsible More or less headache is always associated with chronic sinus disease Its severity may bear no relation to the severity of the nasal lesion, very severe pain often being found with minor nasal changes, and vice versa Nasal headaches are not constant as to severity They are usually intensified by stopping, jarring, prolonged mental work and loss of sleep The location of pain associated with sinus disease is by no means constant, but the patient will usually have the pain in the same region There is a typical headache associated with each sinus

The differential diagnosis between nasal and ocular headaches can usually be made by external observation In sinus disease the headache is usually unilateral, while ocular headaches are nearly always bilateral

Discussion on Headache

Dr Archibald Church We are in doubt as to the mechanism and the physiology which eventuates in a headache I am convinced that a large number of headaches—not all—are due to pressure on the dura, and that the pain is in the dura In some patients I have had the opportunity of manipulating the dura with the patient conscious and have applied electrodes over the dura and through the dura and have stimulated the cortex centers without producing the slightest discomfort at the point of irritation, but producing all the major phenomena that would be obtained by the simple application of the electrodes to the uncovered cortex In one instance in which the dura had been opened for the exploration of the cortex, the patient being conscious, I found that I could cut the dura with a pair of scissors, with only the slightest discomfort to the patient It could be transfixed or cut with a sharp knife without producing any pain, but if I seized it with hemostatic forceps, producing pressure, some discomfort was produced

It would seem that the dura reacts something like the bowel, that pressure conditions produce discomfort and perhaps pain Therefore in all probability in cases of brain tumor the actual pressure of the growth in the cranial cavity produces the headache seen in these cases, which is relieved by decompressive operations or spinal puncture Many patients complain bitterly of pain after lumbar puncture, which is probably due to the fact that after the needle is withdrawn there is a leaking of the fluid through the opening left by the needle So I would strongly advise the use of a very fine needle, preferably a very thin iridium platinum needle

The peculiar condition of so called indurative headache is worth some consideration Ettinger recently insisted that 60 per cent of the chronic headaches are due to indurative conditions in the aponeurosis of the muscles that actuate the scalp, the occipitofrontalis particularly I share Dr Preble's experience in not being able to detect these cases, but I have found that in a proportion of these patients past middle life, the condition is associated with rheumatoid processes or gouty conditions

Another type of headaches which seems to be becoming more frequent is those associated with high arterial tension, in which there is no evidence of kidney lesion merely a low specific gravity of the urine, headache experienced on waking, continuing through the day and subsiding at sunset This condition I have found to be amenable to those measures which reduce arterial tension

The cases of nasal headaches with which I have come in contact, especially in association with sinus diseases, have usually been unilateral and have presented a headache with which the patient rises in the morning which tends to subside at 10 or 11 in the morning As to the periodicity of headache I, of course, bear in mind the tendency of syphilis to produce a nocturnal headache, but I have frequently seen syphilitic headaches which occurred in the morning Malarial headaches commonly occur before midday, but this may be broken up by a few doses of quinin, and the headache will come after the noon hour I have never seen a case of headache which was distinctly of a reflex character from eye conditions that was not provoked by the use of the eyes under certain conditions At present we have a remarkable demonstration of this in the moving pictures Some persons will have headache after fifteen minutes' watching The jiggling pictures produce a headache with startling rapidity, as a rule, but the history in such cases will show that the headaches date back to the time when the child first used his eyes for the near point

I am glad that the point of heredity has been mentioned with reference to migraine There is no disease which is so hereditary as migraine I once called attention to the epileptic features in migraine For a long time I thought a patient of mine had petit mal attacks, but proper management led me to the final diagnosis of a migraine I have a case now in which the attack commences with a tingling in the head, shortly after this the side of the face seems to be drawn, speech is thick, and there is distinct aphasia The right leg also drags a little This lasts for fifteen or twenty minutes, and in about half an hour severe headache comes on, followed by all the vasomotor phenomena of migraine Migraine is a distinctly psychoneurotic disorder, and essentially hereditary, so that it is important to remember that in making this diagnosis you must have a history extending back into the lives of the antecedents

There is no problem that requires more thorough and searching investigation than the origin of headaches and there is no condition so unimportant that it can be overlooked in any case of headache

Dr Harry Kahn In a frontal sinus disease there may be headache in the occipital region or headache from ethmoidal disease may be manifested in any part of the head There is no definite location, except probably in acute frontal sinus disease One point worth noting in frontal sinus disease is that patients have a band like pain in the morning, which is especially accentuated when working hard When the nose is cleaned out, the headache disappears, and by the middle of the day is gone, but this band like pain is very definite I have seen patients with chronic nasal suppuration who never had any headache A patient may have a chronic nasal discharge and pus in the nose without suffering from headache People also may have ozena for years without headache

There is a headache which is noticed in otologic work in which a year or six months after a patient has had the mastoid opened a headache appears, which is probably due to a shrinking or pressure on the dura This headache seems to be intractable Then, again, I have seen another form, a headache due to disease of the sphenoid sinus, in which there was simply a hypertrophic condition of the sphenoid sinus There is also a headache due to inflammation of the sphenopalatine ganglion, presenting definite symptoms of pain in the head, which has been treated by injections of alcohol into the sphenopalatine ganglion through the nose

Dr Robert Sonnenschein One of the most definite things about the localization of pain with reference to certain sinuses is the fact that no one sinus shows any characteristic reference of the pain, except that infection of the antrum usually causes pain in or about the cheek In cases of vacuum headache, especially those affecting the frontal sinus, there is a very distinct point of tenderness at the inner angle of the eye Pressure on the floor of the frontal sinus at that point causes excruciating pain Attention has been called by Halle of Berlin to a peculiar headache complained of by many persons, especially neurasthenics, and noticed mostly on arising This pain is located at the base of the skull, where the muscles are attached to the occipital bones, and characterized by the fact that massage with considerable pressure relieves it It is of no significance so far as lesions of the sinuses are concerned, but a point to be remembered in those cases of intractable headache occurring especially on arising

Dr C H Lovewell The form of headache due to constipation comes under the head of a toxic process, but, after all, it is the one most commonly seen in our general practice Just what we should do in these cases is a puzzle The patients almost invariably have taken all sorts of headache remedies, and only when they fear that they are becoming addicted to the use of these drugs do they consult the physician The druggist really is the man who can tell you about headaches because he is the one who sees most of them

Dr R B Preble I just want to refer to one point mentioned by Dr Church namely the reduction of arterial tension in these cases with high arterial tension If the tension can be reduced by a regulation of the diet and the manner of living it is all right, but it should not be brought down by the use of nitroglycerin

28. **Enzyme Activity of Duodenal Contents.**—Active amylolytic, lipolytic and proteolytic enzymes were found by Chace and Myers to be present in duodenal juice, though the activity of these enzymes is apparently subject to considerable variation under normal conditions. The acidity of the gastric juice appears to be without influence on the activity of the enzymes present in the duodenal juice. In a case of carcinoma of the gall-ducts and pylorus with biliary obstruction, there was an entire absence of bile from the duodenal juice. In a case of chronic pancreatitis, the amylolytic and proteolytic activity was entirely negative, while the lipolytic activity was comparatively weak. The absence of pancreatic enzymes from the duodenal juice would appear to be positive evidence of either pancreatitis or non-potency of the pancreatic ducts, while the lack of bile would appear to afford similar evidence of the occlusion of the common bile-duct. Further observations on these conditions are desirable.

29. **Hemorrhagic Disease.**—True hemorrhagic disease, Whipple says, is rarely associated with simple obstructive icterus, contrary to common belief. Delayed coagulation time in jaundice may be influenced favorably by calcium, but such cases do not suffer from bleeding unless there is some other abnormality—for example, an excess of antithrombin. In these rare cases of true hemorrhagic disease associated with profound icterus, Whipple presupposes some liver disease and an upset in the antithrombin-prothrombin balance. Calcium has no effect on this condition. Disease of the blood-forming organs may present symptoms of hemorrhagic disease because of an excess of antithrombin in the blood. Whipple believes that it is unlikely that the blood-forming tissues are directly concerned in the antithrombin production, as this element is much in excess in the case of anemia with complete marrow aplasia. He regards it as being possible that the products of blood-cell disintegration may stimulate an overproduction of antithrombin, and probable that the majority of hemorrhagic cases and purpuras associated with leukemias and anemias belong in the antithrombin group. Melena neonatorum in many, perhaps all, instances is characterized by a relatively sudden disappearance of prothrombin from the blood. This condition usually develops during the first two weeks of life and is often fatal. The cases react favorably to fresh serum treatment.

Whipple advises that the treatment of hemorrhagic disease should follow a careful analysis of the blood, as harm can be done by faulty treatment. In cases of low or absent prothrombin, serum which is rich in this element is indicated. It should be given intravenously if possible. Direct transfusion is of even greater value. Treatment of antithrombin cases offers great difficulties. Serum treatment offers no help and it may even stimulate a still greater overproduction of antithrombin. Indirect transfusion is open to the same criticism, as large amounts of thrombin are introduced. If the means by which the antithrombin is neutralized or used up in the normal body can be found out by various animal experiments, the solution of this problem in treatment of antithrombin cases may be reached. At present direct transfusion seems to offer the greatest hope of permanent benefit.

30. **So-Called Syphilis "Antigens."**—In the order of efficiency in the practical serum diagnosis of syphilis the authors arrange the various extracts as follows: 1. Cholesterinized alcoholic extracts of human, pig and beef heart, named in the order of efficiency and safety. It should be remembered that these extracts may yield slight degrees of inhibition of hemolysis with normal serums and must therefore be carefully controlled. Cholesterinized alcoholic extracts of syphilitic liver have the advantages of cholesterin and any additional product of the *Treponema pallidum* which may be present. 2. Plain alcoholic extracts of known syphilitic liver. 3. Acetone-insoluble lipoids (Noguchi). 4. Plain alcoholic extracts of human, pig and beef heart. 5. Acetone extract of syphilitic liver. 6. Plain alcoholic extract of normal liver.

The authors claim that best results are secured in the practical serum diagnosis of syphilis by using several "antigens" with each serum, including plain and cholesterinized extracts. This increases the amount of work and the quantities of the various components of the reaction, but results warrant the former and the latter is readily overcome by using just half the quantities of Wassermann's original technic. Thus 0.1 c.c. of serum may be used with each "antigen" instead of the usual 0.2 c.c., the quantities of complement, amboceptor and corpuscle suspension being equally divided. In this manner 1.0 c.c. of serum (2 to 3 c.c. blood) will be sufficient for conducting the Wassermann and Noguchi reactions with at least two to four "antigens," including the usual serum controls.

31. **Blood-Flow in Hands and Feet with Obvious Anatomic Differences.**—In a man with healing burns on the hands Stewart found that the apparently great vascularity of the new tissue did not correspond to an abnormally great flow. Certain phenomena interpreted as due to a peculiar vasomotor instability of the new vessels were observed in testing the vasomotor reflexes. A relatively good flow in the feet was seen in a man with great and persistent edema of both legs in whom a diagnosis of Hodgkin's disease was made. This was interpreted as indicating obstruction rather on the lymph path than on the venous path. Three cases of unilateral inflammation in the hand, one bacterial and two non-bacterial (gout and a sprain) were compared. The flow in the infected hand was increased, while in the normal hand it was diminished. In the case of gout, while the flow in the inflamed hand was greater than in the normal hand the difference was much less than in the case of infection. The contralateral vasoconstrictor reflexes from the normal to the inflamed hand were very slight in the case of the infected hand, of normal intensity in the case of gout. It is suggested that this indicates the existence of a relative vasoconstrictor block in bacterial inflammation in the interests of a permanently large flow of blood to combat the infection. Temporary anemia of the hand (produced by bandaging) was followed by a moderate increase in the flow in a normal man.

In cases of congenital differences or differences originating in early life between the two hands, the blood-flow in the defective hand corresponded to its functional condition, being of normal magnitude when the power of the hand was good. In a case in which some of the fingers of one hand had been lost by amputation, the flow per unit of volume was distinctly less in the defective than in the intact hand. This is mainly because the surface of the fingers is, in proportion to their bulk, so much greater than that of the rest of the hand. It is for the same reason that the flow per unit of volume is much greater in the distal half of the normal hand than in the hand as a whole. In a case in which the innominate and the right common carotid arteries had been ligated one month previously, the flow in the right hand was two-sevenths of that in the left, although no pulse could be felt in the radial. Sixteen weeks later the ratio had risen to 1 : 1.3, the flow in the left hand being normal in amount.

32. **Blood-Transfusion and Regeneration in Pernicious Anemia.**—The transfusion of physiologically unaltered blood is held by Vogel and McCurdy to be one of the most promising forms of palliative treatment available in pernicious anemia. The number of cases on record in which a remission of notable degree and considerable duration has followed immediately on a transfusion is so great as to make it impossible to regard these results merely as coincidences. If proper precautions are taken to select a healthy donor and by the usual tests for isohemolysins and isoagglutinins the serum and corpuscles of donor and recipient are found mutually congenial, there is no danger, and the measure should be employed earlier in the disease instead of waiting until the patient is in a desperate condition There is evidence in favor of the view that greater judgment and accuracy are needed in determining the amount of blood to be transferred. It is quite possible that too large an amount of transferred blood may be injurious, and that more benefit is to be expected from small doses introduced at intervals to be determined by the progress of the patient. The enumeration of the reticulated cells by means of the method of vital staining affords a useful means of gauging the hemopoietic activity of the bone marrow, and by watching the patient's progress in this way the indications for and effects of various therapeutic measures can be well determined and supervised.

33. **Pathogenesis of Contracted Kidney.**—In the severe forms of nephritis, Aschoff says oliguria depends on a glomerular disease and not on a disease of the blood vessels. Also the polyuria, both in the nephritic as well as in the vascular contracted kidney, in so far as the histologic findings seem to indicate, does not depend on a hypersensitiveness of the still diseased vessels, but on the increased work of the undamaged vessels and their respective filter apparatus, or the only slightly damaged ones, or those which have entirely recovered from their damage.

These forms of polyuria are compensatory or accommodative in nature and, he says, must be sharply distinguished from the acute irritative polyurias of toxic origin. The latter depend on a local damage to the blood-vessel filter apparatus, the former on a functional accommodation, usually accompanied by simultaneous accommodative processes in the rest of the general vascular system. Aschoff emphasizes that the problem of acute nephritis is entirely different from that of the chronic nephropathies, just as in toxicology the problem of acute poisonings differs from that of the chronic. In the acute nephritides we have to do with the question of an acute damage to previously normal functions; in the chronic nephropathies the question is that of the possibilities for compensation and of a failure of these compensatory regulations.

35. **Urinary Nitrogen Affected by Desiccated Thyroid.**—The administration of desiccated thyroid to four patients with dementia praecox caused: (1) an increase in the output of total urinary nitrogen; (2) an increase in the output of creatinin; (3) an increase in the output of indol-acetic acid.

36. **Blood in Epidemic Parotitis.**—In uncomplicated cases of epidemic parotitis, Barach says, the leukocytes are affected in the following manner: By the time the disease has manifested itself—even though the parotitis is not yet developed—a leukopenia is present. The number of lymphocytes is moderately increased and the polynuclears have fallen below normal. When the parotitis is fully developed there is a marked leukopenia, most marked in the cases with the higher temperature and greater parotid involvement. In this leukopenia the polynuclears are relatively and absolutely decreased, the mononuclears are relatively and absolutely increased. As the disease subsides the total number of leukocytes, the polynuclears and mononuclears revert toward their normal proportion. The eosinophils, which are scarcely seen during the activity of the disease, are found in about their usual numbers as the blood returns toward the normal.

37. **Hypertensive Cardiovascular Disease.**—The most prominent symptoms associated with high blood-pressure according to Janeway are circulatory rather than renal. The disease underlying high arterial pressure is predominantly a disease of the circulatory system, and is best designated hypertensive cardiovascular disease, either primary or secondary when preceded by an inflammatory nephritis. Death in this type of cardiovascular disease, among patients in private practice, occurs in the following ways, arranged in the order of their frequency: First, by gradual cardiac insufficiency; second, with uremic symptoms; third, by apoplexy; fourth, from some complicating acute infection; fifth, in an attack of angina pectoris; sixth, from purely accidental and unrelated causes; seventh, in a paroxysm of acute edema of the lungs; eighth, after the manner of cachexia. The early symptoms associated with hypertensive cardiovascular disease have an important prognostic significance which can be utilized therapeutically, particularly for the institution of safeguarding treatment. The early occurrence of symptoms of myocardial weakness, especially dyspnea, indicates a more than 50 per cent. probability of an eventual death by cardiac insufficiency. In these patients, to safeguard the heart is the main therapeutic indication. The early occurrence of anginoid pain on exertion does not indicate a probability of death in an anginal paroxysm for more than one-third of the patients. It does indicate a probable cardiac death of some type. The therapeutic indications here are similar to the foregoing, except as modified by the existence of syphilitic aortitis. Anginal attacks as compared with other cardiac symptoms do not materially affect the expectancy of life.

Polyuria, particularly if nocturnal, indicates the probability of a uremic death for more than 50 per cent. of the patients. It is not essential to safeguard the heart in these patients, unless associated cardiac symptoms exist. Headache, especially that heretofore described as typical, indicates the probability of a uremic death for more than 50 per cent. of the patients, and of the death from apoplexy for a considerable number of the remainder. The therapeutic indications are similar to those of polyuria. Loss of flesh, if marked and progressive, is a symptom of bad prognostic import. The relation of the height of the blood-pressure to prognosis is doubtful. Systolic pressures persistently well above 200 mm. Hg seem to indicate a greater probability of death by uremia or apoplexy. The exact height of the blood-pressure does not seem to have much bearing on the expectancy of life.

The average duration of life in this group of patients, after the onset of symptoms associated with high blood-pressure, has been four years for the men and five for the women. One-half of the whole number of deceased died during the first five years. One-quarter of the number lived between five and ten years, and the remaining quarter over ten years from the appearance of the first symptom. The existence of this considerable number of patients living for a long period of time suggests the need of great caution in making a prognosis as to expectancy of life.

45 *Picric Acid as Aid in Treatment of Various Skin Lesions. H. B. Wilcox, New York.

45. **Picric Acid in Skin Lesions.**—As an aid in the relief of discomfort attendant on skin lesions and in the production of a cure in them, Wilcox says picric acid has proved its

worth, in some cases being almost a specific and usually of very great assistance. The danger of untoward results by absorption is negligible. The drug is safe and easy to handle, the only drawback being the permanent staining of everything with which it comes in contact. Better results were obtained in the acute than in the chronic eczemas; most striking was the improvement seen in the acute cases having profuse exudation, excoriation and crusting. In the milder cases an aqueous solution painted on several times daily and allowed to dry was used, while in the more severe cases wet dressings of picric acid were applied, held in place by a facial mask. Lessening of the itching and pain attendant on the inflammatory condition was almost immediate. Reduction in the serous exudation and softening of the crusts were equally prompt. Improvement in the induration was rapid, as was the subsequent epithelialization. Such a rapid relief of the suffering attendant on this distressing condition was not obtained by any other means. Picric acid alone was not as efficacious in the subacute and chronic types of the disease; it was found, however, that the curing of the lesions was hastened materially by treatment initiated by two or three days' application of the picric acid solution. The effectiveness of the usual ointments, containing zinc, tar, salicylic acid, calomel, mercury, etc., was much greater than without this preliminary treatment.

Intertrigo was treated with picric acid. The solution was painted on the surfaces of the skin involved and they were kept from coming into contact by thin layers of absorbent cotton. In the more severely infected cases wet dressings were used. Cures were effected in about half the time taken on similar cases treated with ichthyol solutions. The use of picric acid in intertrigo was so satisfactory that a bottle of the aqueous solution is now part of the regular equipment of the dressing carriage, and the nurses, in the routine of changing the babies' napkins, apply it whenever the buttocks appear red or irritated.

Results in the treatment of erysipelas were not uniformly successful. In certain ways they were, however, more satisfactory than the results obtained by the use of any other method. The discomfort and pain attendant on the condition were relieved more quickly and the edema disappeared rapidly. In several cases, desquamation in cast-like masses followed the use of picric acid, leaving a healthy normal skin beneath. A reduction in the temperature in these patients was the rule, occurring with or without marked improvement in the local condition.

In herpes labialis a more rapid drying up of the lesion and fewer extensions of the trouble were obtained with picric acid than with any other method used. With the exception of immediate and constant relief from the itching, children suffering from psoriasis showed no particular response to the treatment. In impetigo, better results were obtained with the use of antiseptic ointments than with picric acid washes. Picric acid ointments were not used on these cases.

53 *Symposium on Reportability and Control of Venereal Diseases. S. L Strong, Boston.

46. **Diagnosis of Gall-Bladder Disease.**—A history of indigestion which manifests itself soon after eating by a sense of fulness and the eructation of gas; by attacks of pain of sudden origin in the upper right quadrant passing across the abdomen and around to the back and perhaps to the right shoulder-blade, and which are relieved by vomiting; and the *finding of marked localized tenderness on palpation* when the patient takes a deep breath; certainly suggest gall-bladder trouble. If we have added to these severe colic requiring morphin for relief and followed by a transient jaundice, we are quite justified in making a diagnosis of gall-stones. Gibbon, however, cites cases to illustrate that a patient can have all of these and still not have gall-stones.

47. **Condition of Abdomen and Disease of Gall-Bladder.**—Stockton says a sufferer from infection of the urinary tract may fail to improve with antiseptics or vaccines, but when diet, baths, recreation and open air life are added to the course of treatment, immediate improvement is to be observed. Similar facts are true of diseases of the gall-bladder. It is particularly true because of the close relationship between the gall-bladder and the liver, and the liver, more than any other single organ, feels first the evil results of metabolic deficiency and the harmful effects of the lithemic and gouty diathesis. Attention is directed by Stockton to the importance once attributed to latent gout, to lithemia and to oxalemia. However, these neglected subjects were, and yet are, worthy of closest study. He says that this generation will scarcely listen to one who advises a course of colchicum, alkalies, *a diet scientifically prescribed, systematic diaphoretic* baths, massage and out-of-door exercise in the cure of infection of the urinary or biliary tract, but surely the time is at hand when the obscure subjects of gout, oxalemia and other metabolic defects will stand again in the foreground, not only in explaining pathogenesis, but in guiding therapeutics.

53. **Venereal Diseases.**—In the early months of 1913 letters were sent by Strong to some fifty physicians in Massachusetts and other states to ascertain the prevailing opinions regarding the reportability and control of venereal diseases by boards of health. As to belief in the reportability and control of venereal diseases by the boards of health this canvass would seem to show that a majority of physicians do believe in it at the present time. On the matter of practical adaptation and enforcement the profession is about equally divided, the prevailing view being that more efficient means of treating these diseases in hospitals must be provided before such a move can be taken. Venereal diseases cannot probably be controlled to the same degree as small-pox, scarlet fever, diphtheria, etc., for some time to come. The desirability of gathering more accurate statistics regarding the efficiency of the treatment of venereal diseases is widely recognized. This should be done by societies already existing or by the formation of new organizations with this special object.

61. **Hernia in Children.**—Ochsner points out that approximately 95 per cent. of all cases of hernia in children will

heal spontaneously if the abnormal intra abdominal pressure is relieved and the hernial sac is kept empty This can be accomplished by means of trusses or much more rapidly in inguinal and femoral hernia, by placing the child in bed with the foot of the bed elevated, the time required usually does not exceed six weeks and in most cases the hernia will heal by relieving the abnormal intra abdominal pressure and simply placing the child in bed with the foot of the bed elevated each night from 6 p m to 8 a m for several months Children with a tendency to the formation of hernia should be guarded against developing coughs Their diet should be given at regular times and chosen with a view to avoiding gaseous distention Constipation should be entirely prevented In case of boys, phimosis should be relieved if present by operation Badly nourished and badly cared for children of the poor should be treated in hospitals, being placed in bed in the Trendelenburg position, the cause of increased intra abdominal pressure being removed at the same time by proper diet and treatment Operation is indicated (a) in strangulated hernia, (b) in irreducible hernia due to adhesions, (c) in case the opening is unusually large in a free hernia, especially if the condition is hereditary, (d) in reducible hydrocele, (e) in cases with undescended testicle unless they show a tendency toward spontaneous cure

64 **Vaccine and Serum Therapy**—Kreuscher concludes his paper as follows Biologic therapy will in a short time, it is believed, revolutionize the present day treatment of many medical and surgical lesions, and particularly in the early acute infections Vaccines have failed in many instances to give the desired results because they were given in cases for which they were never intended Autogenous vaccines should always be given when it is possible to obtain them, but that there are cases in which there is a positive indication for mixed vaccines and occasional cases for stock vaccines Vaccines must not be expected to reconstruct tissues, organs or joints that have been destroyed by known or unknown pathogenic organisms That they are prophylactic against such destruction and to be effective must be timely and intelligently administered Vaccines and serums although now used as adjuncts in medical and surgical therapy, have done much to relieve suffering humanity, and have made producers of many who would otherwise have been burdens to society

Kreuscher reports good results from vaccine therapy in a large variety of cases such as acne, furunculosis and carbunculosis, and infections of the lymph nodes, chronic rhinitis, asthma, hay fever bronchitis, empyema, and tuberculosis with mixed infection, osteomyelitis and infected surgical wounds of all descriptions, chronic enteritis and kidney and bladder infections not associated with obstruction by foreign bodies, low grade pyogenic or saprophytic infections and acute and chronic joint infections In ninety cases of arthritis, three classes were distinguished (1) That type of deforming arthritis of gradual and insidious onset from which no organism can be obtained, either from the joints or from the blood stream, or from the secretions or excretions (2) Those cases mostly of the chronic variety, which had their origin in ancient infections of the mouth, pharynx, tonsils respiratory tract, intestinal tract, from which it was impossible to obtain any one specific organism at the time the patients came for treatment, but which yielded to mixed vaccines (3) Those patients with acute or chronic infections of the joints in which a distinct causative organism or organisms could not be isolated

71 Metabolism of Dermatitis Herpetiformis and Prurigo Their Relation to Anaphylaxis H J Schwartz New York
72 Attempt to Determine Bacterial Etiology of Acne with Complement Fixation Reaction M Haase, Memphis Tenn

70 **Vaccine Therapy**—Gilchrist speaks of his six years of experience with vaccine therapy in the treatment of cutaneous diseases (about 800 cases) He has had brilliant results, moderate successes and many failures, probably about in equal proportions He emphasizes that whenever an organism is obtained in pure culture from a case of skin disease, it is only proper that an autogenous vaccine should be used, especially if it is chronic or subacute, or, when the disease is acute, and it does not yield to the usual modes of treatment and becomes dangerous It is still necessary to pay careful attention to diet, to the regular functions of the body, to other internal and external treatments, as well as the application of Roentgen rays in some cases Many infectious diseases of the skin do not require vaccines at all, as, for example, impetigo contagiosa, in which in the very large majority of the cases local applications cause the lesions to disappear in a few days Vaccines are of the greatest value in chronic or subacute and especially relapsing staphylococcic affections of the skin, where there is a lack of production of antibodies being worn out Vaccines are of great value in the treatment of relapsing furunculosis, sycosis vulgaris, pustular dermatitis and folliculitis

In the various forms of eczema the results vary, and Gilchrist says that if a case of pustular, weeping or vesicular eczema is chronic, or relapses, and does not yield rapidly to the usual treatment, then vaccines should be tried In rosacea the treatment yielded some very marked results In connection with acne vulgaris, vaccine therapy has proved to be of great value in the treatment As the result of his experience in the treatment of about 400 cases of acne, Gilchrist finds that a stock *bacillus acne* vaccine made in the hospital laboratory is as efficacious as an autogenous one Gilchrist has also used ointments made up with various skin organisms successfully It appears as if a localized immunity was produced by the application of such ointments The use of a filtrate from living organism was tried with some success in three cases of blastomycosis Filtrates from the staphylococci were also used in staphylococcic affections, but not with beneficial results

104. Carcinoma Question as It Pertains to Uterus.—Barrett emphasizes the following points

1 The epithelial cell reaction, known as carcinoma, is probably due to a microorganism or agent yet unknown 2 The cell reaction now known as carcinoma may prove to be a primarily protective tissue reaction against the cancer infection 3 Women come to the age of frequency of cancer with many benign conditions which serve an opportunity for the introduction of this agent or furnish the irritation which lights up the malignant proliferating process, or both 4 Proper attention to these conditions would decidedly reduce cancer of the uterus 5 These conditions receive a large amount of neglect from the profession and the laity 6 Correction of pelvic pathology as it occurs, and especially as a woman nears the end of the child bearing period will lessen her chances of developing cancer and will otherwise vastly increase her comfort during the 25 or 40 years of life she should have remaining 7 There is a fair chance of eradicating early cancer, with almost no chance of other than ameliorating late cancer 8 Education of the profession and of the public on these points is sorely needed 9 Honesty and intelligence should combine not to watch precancerous suspicious, or early cancer pathology, but to eradicate pathology whether benign or malignant In other words pathology has no place in the human body much less in an organ of great cancer frequency We know no tumor, swelling, erosion, ulceration, cystic degeneration, or irritation that is best to go untreated; if it does not yield to simpler means it should be removed 10 Early radical removal is at present our best method of attack when cancer has once begun, but it is not ideal We may hope for a better method 11 Late cancer can often be checked, symptoms ameliorated nutrition improved comparative comfort restored, life prolonged and perhaps occasionally the cancer completely eradicated by single or repeated cauterization and the same results are claimed on good authority for other measures but these do not offer enough hope to displace early surgical measures 12 Surgery must find its greatest success, not in more radical removal, but in earlier opportunity

107 Diagnosis of Tuberculosis by Sputum Examinations—In utilizing the method of separating the tubercle bacilli by treating the sputum simply with an equal volume of saturated aqueous solution of common salt, thoroughly shaking and allowing to stand for six hours, then skimming the surface with the platinum loop and making therewith a smear on a slide, and stained either slowly in the cold or if time is an object by hot stains, Davis believes that a distinctly advantageous and accurate method for the routine diagnosis of *Bacillus tuberculosis* in sputum is offered No special apparatus such as shaker or centrifuge is required, the proven accuracy of findings is 99 per cent (the superior of any other method yet brought forward for comparative valuation) and it would be possible for the attending physician to himself treat the sputum, skim the surface and make the smear on the slide which would then be all that would be requisite to forward to the laboratory for the expert diagnostic stain and examination

If time is a factor in the technic of staining for microscopic diagnosis resort to hot staining is recommended, and in this case, as soon as the specimen is fixed on the slide, immerse the slide in the carbol fuchsin stain, itself maintained in a hot water bath at 100 C Allow to remain in the hot stain for three minutes, remove and wash with tap water Decolorize cold with acid alcohol for eight seconds Wash with tap water and stain with cold methylene blue for one minute, wash thoroughly with tap water and dry the specimen, now ready for the microscopic examination

109 Vaccine Therapy of Pertussis.—Pertussis vaccine, used by Luttinger in ten cases of whooping cough apparently reduced the severity and shortened the duration of the disease To be effective, Luttinger says the vaccine should be given in much larger doses and at shorter intervals than hitherto recommended A dose of 50 000,000 bacteria should be tested as a prophylactic.

121 Epilepsy.—The advantages of state institutions for epileptics are enumerated by Mullan as follows

1 For economic reasons, a collection of patients in a colony or hospital can receive the most modern care and treatment, the like of which could not be furnished to an individual 2 The patients in such a place lead a well regulated life under careful supervision Exercise, amusement, food baths work, medication etc, are carefully prescribed to suit individual cases 3 The patients have the benefit of experienced physicians and nurses who are constantly becoming more expert 4 'Idleness is the devil's workshop," is especially true in regard to epileptics At these colonies various kinds of work can be afforded as best suited to the degree of learning and need of the individual On colony farms, outdoor work, which is so beneficial, can be afforded Farm work, gardening, dairy work, poultry raising, can be indulged in, and the progress of dementia is thus retarded 5 The colony is able to maintain a graded school with trained and experienced teachers 6 In a few instances patients who are doing fairly well may be granted furloughs These frequently act as real stimulants to the epileptics, and their visits home, often in an improved condition are appreciated by their relatives 7 Being fellow sufferers the epileptics have sympathies and interests in common They are thus enabled to bear their sorrows more patiently, and life is made comparatively happy for them 8 In colony life their physical and mental condition actually improves This is frequently shown by the thin and delicate becoming stout and resisting soon after their arrival The seizures become less severe and the interval between them often lengthens In fact, their lives are prolonged 9 In independent colonies the epileptic, on account of his physical or mental fit, will not afford an objectionable sight to the feebleminded or other invalids with whom he is now often housed 10 In such institutions the sexes can be separated which is such an important step in preventing the reproduction of epileptics and other defectives 11 Being together in large numbers they afford the opportunity for clinical pathological and therapeutic research Such research is benefiting and will continue to benefit epileptics and it will be instrumental in diminishing the incidence of this dreadful malady

At present in thirty four states (including the District of Columbia), epileptics are cared for in public and private hospitals, sanatoriums, institutions for incurables, pauper asylums and homes State hospitals or colonies established solely for the purpose of treating and caring for epileptics are nine in number They are located in Connecticut, Indiana, Kansas Massachusetts, New Jersey, New York, Ohio, Texas and Virginia Other state institutions in which epileptics are cared for are in Michigan, Minnesota, Missouri, North Carolina and Wyoming The following states now have laws which wholly or in part prohibit the marriage of epileptics: Connecticut, Indiana, Kansas, Michigan, Minnesota, New Jersey, Ohio, Utah and Washington.

11. **Acute Pancreatitis.**—This condition in the authors' opinion is caused by the entrance of bile or duodenal contents into the pancreatic duct, which there activates the pancreatic ferment and causes a digestion of the gland, a circumstance which may be followed by the invasion of microorganisms. In some cases this digestion apparently takes place without any invasion by microorganisms. This digestion in the gland affects the blood-vessels, leading to hemorrhage in and around the gland. This process then spreads beyond the confines of the gland, leading to the phenomenon of fat necrosis in other parts of the abdomen. It appears that fat necrosis is not seen in cases in which pancreatic juice alone has found its way into the peritoneal cavity, but that when this is mixed with bile the phenomenon occurs. The authors claim that this theory of pancreatitis seems to be borne out by the pathologic findings in their cases, in which all stages of the condition were met with, from the very earliest in which the cells still stain fairly well but are seen to be separated from each other and from the basement membrane, to the most advanced, in which all indication of the structure of the gland has disappeared and only a few nuclear fragments are seen. These conditions, they maintain, are due to the invasion of the gland by bile or bile-containing fluid by way of the ducts. In some of these cases, too, inflammatory reaction and abscess formation were present in addition to the above features, and in these cases they suggest that the gland has been secondarily infected by some microorganism. If this infection does not take place, no inflammatory reaction is seen in the gland at all, and the case is not one of pancreatitis but pancreatic necrosis.

The very acute symptoms observed in these cases is due, they suggest, to the absorption of toxic products of the digestion going on in the gland. Though five of their patients had gall-stones, only one gave a history of biliary colic or jaundice. Three patients had had bad "indigestion" for over a year with or without hematemesis, which made them suspect perforated gastric or duodenal ulcer. In all the cases the condition started suddenly with pain and vomiting, the latter being frequent and copious, as is usually noted. In all the abdomen was rigid and tender; in one case the tenderness was most noticeable in the upper part of the abdomen, and in once case in the left loin. In two cases there was obvious dulness on percussion above the pubes. An extreme degree of collapse was a marked feature in four of the cases. In one case the patient was pulseless at the wrist within twenty-four hours of the onset, and remained so for twenty-four hours after the operation, when she began to improve. Two cases ended fatally within twenty-four hours of the onset of acute symptoms.

12. **Intestinal Obstruction.**—Deanesly emphasizes the following points: Large numbers of patients die every year from intestinal obstruction due entirely to mechanical causes which are remediable by surgical operation and by no other means. The majority of these fatal cases are not operated on until a late stage in the disease, and most of them are in the first instance treated by drugs or applications, internal or external, which cannot possibly give relief. The difficulty of diagnosing the existence of mechanical obstruction is increased by the popular confusion between constipation—that is, temporary suspension of the motor functions of the bowels—and real obstruction—that is, mechanical hindrance at a definite point. The consequences of the latter condition are so serious and so urgent that the question of its existence should be carefully considered in every case of abdominal illness in which pain is associated with vomiting, distention and absence of recent bowel evacuation. If the possibility of obstruction cannot be excluded after a short period of observation, surgical assistance should be obtained as soon as possible. Obstruction of the bowels within the abdomen is just as much a surgical disease as strangulated hernia. The difficulty of the diagnosis in the former merely adds to its dangers, the greatest of which is delay.

16. **Treatment of Tuberculous Peritonitis.**—In two apparently hopeless cases of tuberculous peritonitis in children Lawrie found the administration of the following mixture very beneficial:

		gm. or c.c.		
℞	Calcii carbonatis (precip.)....	8		ʒ ii
	Olei creosoti	2		♏ xxxii
	Mucilaginis tragacanthi q. s.			
	Potassii iodidi	1		gr. xvi
	Saccharini		50	gr. viii
	Olei menthae pip. vel anisi ..		33	♏ v
	Aq. ad	240		℥ viii

Dose.—Two drams every four hours for a child of 5 years.

Tincture of opium or compound tincture of camphor may be added for the relief of pain and diarrhea, if present. The patients were two boys, aged 3 and 5 years, respectively. The younger had large, easily palpable masses in his bulging abdomen, and all the other symptoms well developed. He had been ill for a long time, gradually getting worse, and his parents had been informed that there was little or no hope of recovery. The elder, Lawrie saw eighteen months ago; the intestines and peritoneal glands were matted into one mass about the size of a small football, somewhat irregular in outline, and not only palpable but observable under the abdominal wall. The boy took the mixture, supplemented by petroleum emulsion. A diet of easily digested food, principally of milk, was prescribed.

The first boy who took cod-liver oil emulsion along with the mixture, began at once to improve, and in two months the abdominal tumors had disappeared and his general health vastly improved. There has not been any recurrence, and to-day he is a fine specimen of a strong and healthy boy. The second boy like the first, began to improve directly he came under treatment, and in two months the abdominal mass had shrunk to the size of a tangerine orange, and all the other symptoms, such as fever, pain and diarrhea, disappeared. At the end of another month Lawrie failed to detect any lump at all, and his general condition was much improved. He has continued in good health for over a year, and is a bright and healthy looking lad.

18. **Large Intestine.**—The work of the colon, apart from its use as a storage and expeller of the common refuse, is, so far as Griffiths has been able to discover, (1) to dry the contents as they leave the small intestine, and (2) to get some useful substance out of the refuse while it is mixed and churned and undergoing fermentation with, it may be, disintegration. This substance, though as yet of unknown quality, gives to the body that which it requires for the development of that feeling which is best described as being "in the best of health and spirits"; further, it is something of all important value to the individual. Excess of it is deleterious; lack of it is attended with pronounced changes in general nutrition, and perhaps progressive inanition, leading after a variable time to death from simple loss of vigor and strength.

20. **Traumatic Intramuscular Ossification.**—Traumatic intramuscular ossification ("myositis ossificans"), Morley believes, is due to migration of osteoblasts into adjacent contused muscle and blood-clot, after destruction of the periosteum and loss of its function as a limiting membrane to the growth of bone. It is essentially the same process as callus formation. The condition may be produced experimentally in animals by reproducing the same mechanical conditions by an aseptic open operation. In a case of difficulty in diagnosis from sarcoma, open exploration is advisable. Simple excision is usually, though not invariably, followed by recurrence. Conservative treatment condemns the patient to a long period of disability, which may occasionally be permanent. Excision combined with grafting of deep fascia on to the denuded surface of bone gives the best prospect of rapid and complete recovery, and is urged for all cases not complicated by ossifying periarthritis. Osteoblasts and chondroblasts, Morley says, are the same cells under different conditions of nutrition.

25. **Inguinal Hernia in Child.**—Speaking of the truss treatment of inguinal hernia, Clogg says that the processus vaginalis in normal development should be obliterated at or shortly after birth. Peritoneal development goes on after birth. During development certain layers of peritoneum may fuse together and layers of peritoneum may disappear, and such changes in the peritoneum occur during the first few months of life. The processus vaginalis, being originally peritoneum, may disappear, and such changes in the peritoneum occur during the first few months of life. The processus may conceivably, therefore, undergo complete development after birth, i. e., it may become naturally obliterated. Up to what age such obliterative changes may be anticipated is merely a matter of conjecture. Obliterative changes could obviously not take place if the hernia were allowed to descend. The only possible value of a truss, therefore, is in restraining the descent of the hernia and thus allowing Nature to proceed with normal development. A truss may act, therefore, indirectly in the cure of a hernia. As a direct cure it has no value. Its pressure cannot possibly have any influence in forming acquired adhesions in the sac, which may eventually lead to the cavity disappearing, or even in obliterating the patency of the neck of the sac and excluding it from communication with the peritoneal cavity. During the first few months of life Clogg advises a truss, solely with the object of restraining the hernia, and in order that this may be effective it must be worn constantly. He advises this treatment, except in special circumstances, up to about the fourth or sixth month. If a hernia be seen at this age he deems it exceedingly improbable that a natural cure will result, and in the absence of any contra-indications advises operation.

29. **Heart-Disease in Children.**—In all inflammatory cases in which there is the least suspicion of rheumatism, Cautley says, salicylates and alkalies must be prescribed. The patient is kept in bed on a light milk and carbohydrate diet, fruit and vegetable soups being allowed as a change. Complete rest and a trained nurse are necessary. Blistering or counter-irritants may be used, but are chiefly efficacious in pericarditis. Vaccines and serums are of problematic value. In infective endocarditis—fortunately infrequent in children—Cautley's experience with vaccines and serums has proved unsatisfactory. It is difficult to grow the incriminated organism from the blood, difficult to prove that the organism obtained in cultures is the one causing the disease, and difficult to obtain good results from an autogenous vaccine or from a polyvalent serum. Recourse is sometimes had to paracentesis for the relief of pericardial effusion. It is rarely essential in rheumatic pericarditis, for even the largest effusions may be absorbed. For purulent effusions the pericardium must be opened and drained. Another and more modern operation, sometimes called cardiolysis, is resection of the rib cartilages over the cardiac area, for the relief of general adhesion of the pericardium. The treatment of cardiac failure and backward pressure is the same at all ages. For extreme edema of the lower limbs multiple punctures and sterilized dressings are more satisfactory than the insertion of Southey's tubes. Iron and glycerophosphates are given when compensation is established. Compensation is maintained by regulation of the mode of life, diet, sleep, hygiene and exercise. In every case it is essential to recognize the cause and differentiate the type of cardiac disease and clearly to understand its probable course and prognosis.

30. **Prevention of Mouth-Breathing.**—The apparatus used by James consists of a wire frame over which sheet rubber (dental rubberdam) is stretched; it is placed inside the lips and cheeks, resting on the outer surfaces of the teeth and gums. The wires are fitted and soldered together and then struck between a zinc case and a lead die in order to secure an accurate fit. Gold wire is perhaps the best, but German silver, gilded, is quite serviceable. The apparatus should be sufficiently large that it is steady when in position, extending back to the second premolars. No danger exists from swallowing or displacement with an apparatus of this size. The apparatus is worn only at night except perhaps for a few hours in the day in order that the patient may become accustomed to it, or to determine that nasal respiration is possible. In small children the apparatus may be used in the day without any rubber to prevent thumb-sucking—a habit most conducive to mouth-breathing at night when the thumb is withheld. When the apparatus is in position mouth-breathing is quite impossible. There is little difficulty in quickly removing the apparatus if it should be necessary.

44. **Abderhalden's Test for Pregnancy.**—For experimental purposes the test was applied by Williamson to fifty patients. Of these, twenty women were either in the last three months of pregnancy or had recently been delivered. In each case the

result was positive. Thirty women were not pregnant, in all thirty the reaction was negative. Williamson regards it as established that the serum of pregnant women contains a ferment specific to placental albumen. This ferment can be demonstrated from the eighth week of pregnancy until ten days after delivery. Its presence may be demonstrated by the polarimeter or dialysis. The former method is the more reliable in that the sources of error are fewer. The accurracy of the test depends on the most scrupulous care in details, and it is only in the hands of an expert that the results can be relied on. The ferment is found only when chorionic tissue is present in the body. It is probable that under other conditions the color reactions and optical effects produced by the test may be simulated.

62 Perforation of Gastric Ulcers into Heart: Report of Case. F. E. Tylecote.

54. **Examination of Tuberculous Pleural Fluids.**—The finding of tubercle bacilli, Gloyne says, is the only conclusive evidence of tuberculous infection. In his series of twenty-five cases bacilli were found in 40 per cent. of the serous and 71.43 per cent. of the purulent fluids. Ordinary film preparations are satisfactory in purulent fluids, but in serous more careful measures are often necessary. In large effusions without clot sedimentation and centrifugation of the fluid may be sufficient. When present, the examination of clot offers the best hope of finding bacilli. In serous effusions the next best test is the lymphocyte count. Failing this, the tests in order of value are (*a*) protein content (usually 4 to 6 per cent.) and (*b*) specific gravity (about 1.018). Sterility on ordinary culture media is suggestive of tubercle in purulent fluids. It is not of much value in serous exudates, since some other effusions and most transfusions are also sterile. Secondary infection was only noted in one instance.

Sei-I-Kwai Medical Journal, Tokyo

November, XXXII, No. 11, pp. 127-132

63 *Some Experiments on Transplantation of Cancer in Japanese Mouse. S. Higuchi.

63. **Transplantation of Cancer in Japanese Mouse.**—Higuchi discovered a primary cancer in a Japanese mouse which had continued for thirty generations after transplantation. He injected the primary cancer obtained into the subcutaneous tissue of the axilla of 20 Japanese and 9 English mice. Not one of the English mice showed development, but among the Japanese there were 2 with good results. Of these one was absorbed in a few days and only one continued to grow. This is the first generation and in after experiments only the Japanese mouse tumor was used. This tumor was injected into 20 mice and showed 7 positive results by the seventeenth day. These are the third generation and of these one died on the thirty-first day. The tumors of the remaining 6 gradually grew in size and 2 formed ulcers as the result of necrosis. The tumor (third generation) was injected in 21 mice with 9 positive results by the seventeenth day and these are the fourth generation. Of these, many died or were absorbed, and there were only 3 remaining by the thirty-first day. A tumor from the fourth generation was injected into 15 mice with 9 positive results by the seventeenth day (fifth generation) and 5 remained on the thirty-first day.

A tumor of the fifth generation was injected into 31 mice with 9 positive results by the sixteenth day (sixth generation) and only 6 remained on the thirtieth day. A tumor of the sixth generation was injected into 21 mice with 17 positive results by the seventeenth day (seventh generation) and 13 were still alive on the thirty-first day. A tumor of the seventh generation was injected into 20 mice with 7 positive results by the seventeenth day (eighth generation) and 4 remained on the thirty-first day. A tumor of the eighth generation was injected in 21 mice with 9 positive results by the fifteenth day (ninth generation) and 5 remained alive on the twenty-ninth day. A tumor of the ninth generation was injected into 23 mice with 13 positive by the seventeenth day (tenth generation). The total number of mice used for transplantation was 285 in all. The tumor developed by the seventh day in 109 (38.2 per cent.) and by the thirty-first day in 63, (22.2 per cent.).

In looking over the experience of transplantation during one year, the following facts were obtained by Higuchi. This cancerous tumor was inoculated into the English mouse without any development. The injected tumor gradually grew in size until the third generation and then began to decrease, but again grew larger and became remarkably increased in the tenth generation. The highest number growing after injection was in the seventh generation, i. e., 17 out of 21 (81 per cent.). Then the power of development showed some decrease until the tenth generation, but in this period 13 out of 23 (57 per cent.) showed the positive results and seemed to recover the power. When the tumor grew in size the central part became necrosed and formed an ulcer. Higuchi was able to obtain positive results by injecting the tumor six hours after the death of a mouse.

65. **Solitary Cyst in the Kidney.**—The cyst was as large as a child's head and encroached so much on the pelvis that it had been diagnosed as an ovarian cyst. Microscopic examination after the removal of the kidney revealed tubercle bacilli. The course of the case at the time and later and the integrity of the other kidney and lungs confirmed the assumption that the case was one of unilateral renal tuberculosis casually discovered and removed in time to eradicate the disease from the system.

66. **Conservative or Radical Operative Treatment of Ovarian Cysts.**—Vanverts has never had occasion to regret having left the sound mate in his seventeen cases of cystic disease of one ovary. In fourteen other cases he removed the second ovary and the uterus on account of pathologic conditions in the latter or in the tubes. In one of the cases in the first group he removed the cystic and much degenerated ovary and then cut out from the second ovary the part containing a cyst, leaving the rest intact. The woman has passed through a normal pregnancy since, and mother and child are thriving.

70 Technic for Complete Destruction of the Viscera in Examining for Mineral Poisons. P. Breteau.
71 *Emetin in Ameba Dysentery or Liver Abscess. Dopter.

69. **Decompressive Trephining on Sound Side for Cerebral Hemorrhage.**—Marie reiterates that the apoplectic stroke is comparatively transient as it is due to sudden irruption of blood into the brain. Coma, on the other hand, is the result of pressure on the brain by the blood, and this is permanent unless relief from the pressure is obtained in some way. Profound and persisting coma indicates that both hemispheres of the brain are suffering from compression. If only one hemisphere is affected, the unconsciousness is not so profound. In addition to the compression of the brain by the extravasated

blood, there may be more or less edema from the irritation. For these and other reasons a decompressive operation is indicated, but Marie insists that the trephining should be done on the sound side in certain cases, as this reduces to the minimum the dangers from the operation for the focus of the hemorrhage and the danger of irruption of the blood into the meninges. He warns against any operation of the kind on the elderly on account of possible bronchopulmonary complications. Pronounced albuminuria or profound coma from the start also contra-indicates mere trephining. It is required, however, with apoplexy and conjugated deviation of the head and eyes, when the patient is able to reply with some degree of coherence to questions and no improvement is apparent in twenty-four or forty-eight hours and the breathing suggests the Cheyne-Stokes type and the temperature has gone up a little. All this shows that the pressure on the brain is increasing and that coma is imminent. Prompt trephining of the sound side is the logical treatment, and the results were most excellent in his four cases in which treatment was applied on this principle.

71. **Emetin in Treatment of Ameba Disease.**—Dopter's experience in fifty-one cases has confirmed the invariable destructive action of emetin on the ameba at large, but it seems powerless to affect the encysted specimens. Hence it does not protect against relapses, but the emetin promptly cures the relapse.

80 Pleural Effusion Complicating Therapeutic Pneumothorax. Tecon and Sillig.
81 Renal Tuberculosis Assuming the Form of Lithiasis. C. Perrier.

79. **Exploration of the Internal Ear.**—Joliat reviews in detail the methods of examination at our disposal for testing the functions of the labyrinth, especially those connected with maintaining one's balance, the static function. Disturbances in hearing will locate the trouble if direct visual inspection of the ear reveals nothing. Derangement of the transmitting apparatus raises the lower threshold of the hearing, the bone perception is prolonged and longer than air perception. Derangement of the perceiving apparatus lowers the upper threshold of hearing and causes gaps in the field of hearing, bone perception is shortened and air perception, although shortened, is yet longer than bone perception. If there are subjective sounds in the ear they are more musical and continuous than with deranged transmission. Tests inducing nystagmus will show the condition of the static function and help to distinguish between suppuration in the labyrinth and in the cerebellum. With the latter, spontaneous nystagmus is not influenced by cold water in either ear or turning around or hot water tests. There is no connection between the nystagmus and the falling with eyes shut or deviating in walking. On the other hand, the patient has headache, especially in the morning, the neck is stiff, there is a tendency to choked disk, somnolency, severe dizziness and vomiting and the general condition is impaired much more than with any labyrinth disease. The differentiation is rendered complete by an inability to associate simple movements, especially those in opposite directions, and by the tendency for the limbs to retain any position in which they may be placed. As an abscess in the cerebellum is generally secondary to labyrinthitis, examination along these lines will reveal the extent of the lesion. Spontaneous nystagmus from a cerebellar affection does not change its direction or subside when cold water is injected into the ear on the side toward which the nystagmus is directed. When a change is observed the nystagmus is of labyrinth origin. The technics for the various tests are described in dètail.

*82 *Twin Pregnancy. (Le pronostic de la grossesse et de l'accouchement lorsque l'utérus contient 2 jumeaux.) L. Demelin.*
83 *Serotherapy in Pregnancy Toxic Conditions. P. Gaifami.
84 Extra-Uterine Pregnancy. P. C. Dagneau.

82. **Twin Pregnancy.**—Demelin relates that in 100 twin pregnancies seventy of the 200 children died; all but eleven of those who died were born long before term. The pregnancy was carried to term in only thirty-six cases; abortion occurred in fifteen. The uterus being abnormally distended by the two fetuses is more sensitive to irritation from within and without and consequently it is wisest for the woman to keep in bed when a twin pregnancy is diagnosed beyond question. Twins from a single ovum are less liable to thrive than when each has its placenta, other things being equal. Breech presentation is unusually frequent among twins while it is more serious for them on account of the common debility of a twin fetus while the uterus is more inclined to inertia. The first twin usually suffers most from the birth traumatism as it is cramped in its movements. The two heads locking together in the small pelvis is an extremely rare occurrence. The delivery generally proceeds unusually easy for the woman, but there is a greater tendency to albuminuria and other pregnancy toxic conditions; up to 13 per cent. in his cases. Puerperal complications seem to assume a severe type after twin births, the greater inertia of the uterus and the extra large area of placenta surface and the extra toxic condition in general reduce the resisting power. The great danger is hemorrhage; it is liable to be excessive and the obstetrician's efforts should be directed with special care to prevent this. The main point is to refrain from hastening the delivery of the second twin; the uterus needs time to recuperate from the effort of expelling the first twin. If this resting period is interrupted too soon, the muscular wall will be unable to retract and the blood will flow indefinitely. The spontaneous reappearance of labor pains must be patiently awaited, even though one or two hours or several hours up to several days may elapse. The position of the remaining twin must be supervised and kept favorable for presentation, possibly having a bandage worn until labor starts up anew.

83. **Serotherapy in Toxic Conditions of Pregnancy.**—Gaifami has applied serotherapy in twenty cases of pregnancy toxicosis and states that dermatoses and pruritus in pregnant women were cured in every instance by the serotherapy. The effect was usually favorable also in the uncontrollable vomiting of pregnancy. The results were actually brilliant in his two cases of pregnancy pernicious anemia. The benefit was less constant and striking in albuminuria. The serum from another pregnant woman seems the most effectual form of serotherapy, and all the experiences to date have confirmed the harmlessness of the method.

85 *Errors in Diagnosis of Gall-Stone Disease. F. Lejars.

85. **Errors in the Diagnosis of Gall-Stone Disease.**—Lejars refers merely to old chronic disorders in which either cholelithiasis was erroneously *assumed* or true cholelithiasis was mistaken *for something* else; he reports a number

of instructive cases of each In one, a man of 53 had long had symptoms typical of gall-stones but operation revealed a small cancer on the outside of the lesser curvature of the stomach In other cases old perigastritis with adhesions may cause symptoms typical of gall stone disease, including an apparent tumor in the gall bladder region This perigastritis and the resulting masses simulating a tumor are generally on the left side, and the mass is not so sharply defined, and the edges are more irregular than with a swollen gall bladder Cirrhosis of the liver may develop with colic pains, jaundice and tenderness in the gall bladder region In one such case recently in a woman of 39 the operation revealed the gall-bladder normal, the liver yellowish, knobby and soft He found the gall bladder and ducts also normal in another case in which the laparotomy for recurring "colics" disclosed merely the acute congestion in the liver to which Ortner has recently called attention (See THE JOURNAL, Nov 1, 1913, p 1670)

In another case of true cholelithiasis he found the bile apparatus entirely free from stones at the operation, the very last one of the concrements had probably just been expelled In three recent cases the typical gall bladder colic was caused by simple cholecystitis and there were no concrements, complete recovery followed cholecystectomy. An echinococcus cyst outside the gall bladder or a gumma in this locality may also simulate gall stone trouble, he has operated in two cases of the former In another case a large tumor in the gall bladder region was not accompanied by gall stone symptoms proportional to the size of the tumor, which reached to the umbilicus The Wassermann reaction was negative, but the trouble proved to be a gummatous tumor on the front of the liver The Wassermann test applied later was positive If the possibility of something besides gall stone disease occurs to one, some little anomaly in shape or size will suggest that the case is *not one of ordinary* cholelithiasis Persevering examination of the stool revealing stones or gravel may clear up the diagnosis in dubious cases In any event, the safest rule is to operate

93 98 Surgical Tuberculosis—The methods of treatment applied in Garrè's service at Bonn are described in detail for each class of cases, with the ultimate outcome in all the patients that could be traced to date He warns against the danger of focusing the attention too exclusively on the local trouble and forgetting the importance of general treatment ' This surpasses in importance everything else, regardless of whether operative or conservative measures are applied. In 233 cases of tuberculous spondylitis in the last seventeen years the mortality among the 182 patients that have been traced to date has been 50 per cent for the men and boys and 57 per cent for women and girls, 34 and 38 per cent are cured and 9 and 12 per cent still have something left of their old trouble, among those under observation for at least five years Of those traced for twelve years whose spondylitis began under the age of 10, 40 per cent have died and 10 per cent are uncured, 50 per cent have recovered The course of spondylitis seems to be more malignant in boys, 50 per cent have died of the males developing vertebral caries between 10 and 20 and only 25 per cent seem to be cured at present None has survived of the males acquiring the disease between 15 and 30, injury at work explains this speedy mortality The mortality is highest among women during child bearing age. The duration of the persisting disease ranged from three months to twenty eight years, the average about four years

Trauma, especially in boys, is an important factor and the cases with a history of typhoid have a specially unfavorable prognosis When the tuberculous process is in the upper cervical vertebrae the outcome is speedily fatal in 50 per cent of the cases, while the chances are much better when it is located at the junction of the dorsal and lumbar vertebrae An abscess renders the outlook graver, a fistula is still more serious Operations liable to entail a fistula are, therefore, contra indicated Nervous complications in the elderly generally prove fatal early and render the outlook graver in all cases, but in children the paraplegia is amenable to orthopedic measures Abscesses and paralysis from spondylitis are more common in males Tuberculous complications elsewhere are generally responsible for the fatal outcome; in less than half the cases was the spinal disease the direct or indirect cause of death

99 Roentgen Therapy of Surgical Tuberculosis—Frund relates that five patients were cured and three showed no improvement in a group of eight given mild Roentgen ray exposures for a bone or joint tuberculous lesion On the other hand, only two were benefited out of ten given intensive Roentgen therapy. This treatment was applied in seventy one cases in all, and certain phenomena observed suggest that the tubercle bacilli in some towns are more resistant than in others This seems to be the only explanation of the fact that the same treatment failed so frequently at Bonn, while it gave almost constantly good results at other places with the same technic and roentgenologist

114 *Pernicious Anemia in Pregnancy and the Puerperium A Schüpbach
115 Family Predisposition or Immunity to Diphtheria W Spirig

112 Acute Atony of the Stomach—The acute atony and dilatation of the stomach occurred just after the patient had taken a large dose of castor oil Several liters of fluid were found in the stomach but the patient had not drunk any unusual amount of fluid There was probably excessive secretion of fluid into the stomach, a nervous gastrosuccorrhea superposed on the atony The Roentgen test findings in two convalescents and a healthy man all drinking from 1 to 2½ liters of beer showed that mere overloading does not entail dilatation of the stomach, it may stretch and sag but there are no atony and dilatation For this, some degree of paralysis of the stomach musculature is necessary

114 Pernicious Anemia in Pregnancy and the Puerperium — Schupbach declares that the prognosis of pernicious anemia developing during pregnancy or the puerperium differs from that of pernicious anemia in general, as recovery is possible under arsenic and evacuation of the uterus, spontaneous or induced Nageli has reported complete recovery for eleven years to date in two cases and for five years in another case Two of his patients bore other children later with no return of the anemia The results of recent research suggest that the anemia is due to deficient production of antihemolysins, this assumption is confirmed by the fact that the fetus never seems to suffer from the anemia The mortality is high among the children simply because anemia brings premature delivery Schupbach reports two cases, one in a woman of 25 pregnant for the fourth time During her last pregnancy she had had transient nephritis and the symptoms of the pernicious anemia were ascribed to recurring nephritis at first and thus time was wasted before premature delivery was induced, then too late to save The fetus was well developed, the blood supply was good both in quality and quantity Schupbach knows of no other published report in regard to the findings in the fetus of a mother dying of pernicious anemia Her sister had died a few years before from pernicious anemia The second patient also succumbed not long after delivery induced at the eighth month She had passed through eight pregnancies in eight years, with nine children, and was too weak to rally

116 Severe Acute Anemia —Grober compares acute anemia to albuminuria—both are merely symptoms, and he warns that the exsanguinated appearance may be misleading Only examination of the blood for the proportion of reds and pigment will show whether the trouble is actually anemia or merely the driving in of the blood from the periphery With true anemia the patient is restless, possibly delirious, from the lack of oxygen in the blood, and he gasps for air, the pulse is rapid, small and not quite regular, and systolic anemic murmurs are audible at the apex and pulmonary valve To relieve the sensation of suffocation is the first task, and this can be done by supplying oxygen or by deadening with narcotics the respiration centers Nature attends to the latter by the narcotic action of the carbon dioxid in the blood, any attempt to reenforce this with drugs should be very cautiously done as serious injury may result if the functioning of these centers is permanently reduced In acute anemia it is better to give the oxygen diluted with one half or one third air Relief is usually apparent at once, although when the hemoglobin is already saturated with oxygen it cannot take up any more It is possible, however, that the recently formed red corpuscles in the blood producing organs may be enticed out into the blood stream by their affinity for the oxygen Whatever the theory may be, the unmistakable benefit in certain cases compels us to use oxygen in the dyspneic phase of acute anemia even although it fails to relieve in a certain proportion of cases

The patient gasping for breath often rises up in bed, but this must be prevented on account of increasing the danger from the anemia for the brain He must be kept horizontal or the head lower than the plane of the body This relieves the symptoms from the anemia in the brain, consciousness returns and convulsions cease, but the sensation of suffocation returns and brings the patient up again, his rapid breathing showing how he is starving for air This vicious circle keeps up, often to end in stupor or death unless the patient is quieted with morphin or other narcotic The dose must be small on account of the weakened condition This relieves the suffocation, tranquilizes and gains time for the body to make new blood The artificial means at our disposal for improving the condition in regard to the blood are few and unreliable and fraught with some danger The acute anemia itself is the most powerful of all stimulants for new production of blood provided the blood producing organs are healthy. This is usually the case in anemia from hemorrhage but not with hemolytic and pernicious anemia

For the same reason, transfusion of defibrinated blood seldom gives good results in hemolytic and pernicious anemia while in acute anemia from other causes it is borne well and has proved very useful in Grober's experience Weber's method of repeated transfusion of only 5 or 10 c c blood seems to supply an extra stimulus for production of new blood Autotransfusion may also prove useful, that is, bandaging the limbs from the periphery upward to drive the blood back into the trunk where it is more needed than in the extremities He witnessed great benefit from this in one case of severe intestinal hemorrhage Saline infusion answers about the same purpose, filling the vessels with fluid If physiologic salt solution is not at hand, boiled water can be used, but not distilled water Drop infusion by the rectum can be easily arranged while the patient is still under the influence of the sedative The heart action must be kept good, this may require hot brandy, rum, coffee or flat champagne, or subcutaneous injections of camphor and caffein every hour or half hour, epinephrin in small doses The stomach cannot be depended on and consequently it is useless to give drugs by the mouth, digitalis may fail even by intravenous injection The patient must be kept warm in bed; a prolonged warm bath is often soothing and refreshing Among the local measures to arrest bleeding from a large surface are tamponing with ferric chlorid, gelatin and epinephrin, subcutaneous injection of 40 or 50 c c of a 10 per cent gelatin solution, or injection of 5, 10 or 20 c c of animal or human serum Von den Velden advocates intravenous injection of 3 or 5 c c of a 10 per cent solution of salt, eventually repeated a few times at one or two hour intervals Fresh animal tissue contains large amounts of thrombokinase, so it might prove useful in gastric hemorrhage, given in the form of an infusion of calf's liver An old empiric treatment is to lay a piece of fresh meat on a bleeding surface

117 Meningitis Following Tonsillitis —Siemerling's patient was a boy of 15 and the meningitis developed in connection with a febrile sore throat—a retronasal angina seems to be a regular accompaniment of epidemic meningitis There were two days of headache in this case with a little dizziness and tremor of the hands and then the lad dropped unconscious, delirium alternating with stupor, with other symptoms of severe meningitis Striking benefit followed lumbar puncture which showed the fluid under high pressure The clinical picture was extremely severe but terminated in recovery after nearly two months The fluid contained 300 lymphocytes in 2 c c The fifth week a month's course of mercurial inunctions was commenced using up 63 gm grey ointment. Quincke has called attention to the benefit from mercurial inunctions in serous meningitis

121 Tuberculosis of the Bladder with Intact Kidneys.—Israel's patient was a girl of 22 and the course of the case showed that a tuberculous process in one fallopian tube had spread to involve the bladder After removal of the diseased tube the bladder process healed

122. **Obstetric Hemostasis.**—Zimmerman reports invariable success in arresting hemorrhage after delivery by applying clamps to the parametrium. This stopped all hemorrhage at once even in his five cases of placenta praevia and also with hemorrhage from atony of the uterus. The mouth of the uterus is drawn down to the vulva and the parametrium stretched by pulling to one side and then to the other. Muzeux forceps are introduced along the side and pushed upward close to the side of the vagina and uterus, pushing the vaginal mucosa before the open blades. They are then clamped together, the teeth gripping in the uterus musculature. This is done on both sides and the clamps are left in place for twenty-four hours When they are to be removed the blades are first unlocked for half an hour to see if there is any hemorrhage before removing them altogether. He says that with care to avoid the bladder, this technic is free from danger while it is one of the most effectual means for immediate arrest of serious hemorrhage in threatening cases, especially when the obstetrician has no one to help him. As the procedure naturally is more or less painful, it will be used only after the failure of other measures

128 **Cancer of the Testicle.**—Sakaguchi describes in detail twenty three specimens of cancer of the testicle encountered at the Gottingen pathology institute He reports in addition nine cases in Japan Two of the patients were children of 2½ and 5 and the malignant disease ran a rapid course. The large-celled tumors of epithelial origin formed twenty three of the total thirty two, and the patients were generally between 40 and 60, there was a history of trauma in four cases, but the testicles were in their normal location in all but one instance.

129 **Ligation of Pulmonary Artery in Treatment of Tuberculosis.**—Kawamura reports the end results after ligation of branches of the pulmonary artery in dogs and rabbits, some healthy, some previously infected with tuberculosis In the lobe of the lung thus shut off from the circulation there was great proliferation of the connective tissue and the lobe shriveled and shrank Tuberculous processes in the lobe involved became encapsulated with connective tissue, and there was calcification and scarcely any tubercle bacilli were to be discovered. There were no signs of a hemorrhagic infarct. The method seems applicable for clinical cases provided the tuberculosis is restricted to one lobe and the rest of the lung is sound.

135 *Serum Sickness, 683 Cases L Axenow

135 **Serum Sickness.**—The 683 cases reported were observed at the children's hospital in St. Petersburg and all followed the treatment of scarlet fever with Moser's serum. In the course of seven and one-half years this form of serotherapy was applied in 1,200 cases, and serum sickness followed in 57 per cent. of them, not counting those who died too early for serum sickness to have appeared. It was much more frequent in children under 5 years of age than in older ones. There were twenty-one deaths (3 per cent) due to serum sickness alone. There were thirty-seven others in which besides the serum sickness there were other complications of scarlet fever, making the mortality 8.5 per cent. The serum sickness increases the severity of the complications. Serum treatment for scarlet fever should, therefore, be used very cautiously and only in the severest cases. The symptoms are fever, enlargement of lymph-nodes, joint affections, edema, urticaria and albuminuria. The measures applied in prophylaxis were without result.

146 *Nitrous Oxid and Oxygen Anesthesia (Klinisch experimentelle Versuche mit Lachgas Sauerstoffnarkose) E Zweifel.
147 *Eugenic Indications in Gynecology. M. Hirsch.

146. **Nitrous Oxid and Oxygen Anesthesia.**—Zweifel reviews the literature on nitrous oxid anesthesia and from experimental work and forty clinical cases reaches the conclusion that short operations can be performed painlessly with nitrous oxid, either alone or in combination with oxygen. With or without oxygen it is also adapted for the beginning of chloroform ether anesthesia. The anesthesia may be deepened by giving a sedative the evening before, and again just before the operation. This combination permits the use of this form of anesthesia in a much wider range of cases. He declares that it is the least objectionable form of anesthesia for the patient. There is no feeling of suffocation and hardly ever any excitement or vomiting. It is the least dangerous to life of any anesthetic If the anesthesia is not deep enough, chloroform or ether can be given at any time without injury to the patient.

147. **Eugenic Indications in Gynecology.**—Hirsch believes firmly that the physician, particularly the gynecologist, should take into consideration, not only the welfare of the patient but that of the race, and that reproduction should be prevented by permanent sterilization in diseases that are almost certain to leave bad effects on the children, such as epilepsy, chronic mental diseases, imbecility, chronic alcoholism and morphinism, degenerative forms of neurasthenia and hysteria, advanced stages of tuberculosis, severe forms of exophthalmic goiter and chorea, severe constitutional syphilis and pernicious anemia. In disease where inheritance is uncertain or recovery is possible, he advocates that means for temporary prevention of conception should be taught, declaring that the physician should be a leader in bringing public opinion and the law to an acceptance of such measures as are necessary to protect the race from disease, insanity, prostitution and criminality, for these latter are due to inherited physical or mental defects.

152 *The Secondary Rays in Roentgen Therapy. (Zur Frage der Sekundarstrahlentherapie) G. Schwarz
153 History of Urologic Diagnosis. (Zur Entwicklung der klinischen *Harndiagnostik*) E. Ebstein.

148 **Psychic Depression.**—Kahane discusses various points in psychotherapy, emphasizing that mere persisting worry or anger is liable alone to bring on neuralgia or stomach or intestinal trouble—this seems reasonable when we reflect that intense hyperemia of the skin, that is, a deep blush, may follow a mere spoken word, a fright may induce the most violent contraction of the vessels, driving the blood away from the surface, while expectancy may cause the heart to beat faster and modify the respiration rate. These familiar facts render plausible the assumption that chronic emotional stress may by summation induce complex somatic consequences. The possibility that neuralgia and atony of the stomach or bowel may occur solely as the result of chronic emotional stress amply explains the cure in many such cases by psychotherapy according to Dubois' system.

Kahane deplores the miscredit brought on psychotherapy as a whole by the new school which drags the erotic so prominently into the foreground. He insists that the sexual instinct is nothing more than a subordinate feature of the general instinct for self preservation. Especially with women, the future support, food and shelter, are inextricably bound up in the sentiment of love. In man the erotic flame soon dies down and the comfort of the family table, regular habits, and the warm quiet home—all these are consciously or subconsciously blended in the love passion. Kahane remarks that the overemphasis placed on the erotic in art and literature renders everything that comes from scientific circles bearing on the erotic extremely interesting to the lay public and gives it wide appeal, but, in actual fact, it may safely be asserted that the sexual impulse has no greater sphere in the psyche than the sexual apparatus has in the physical body. Persons who commit suicide under erotic influences are generally those who have failed to make a place in the world, their unfortunate love affair is only the wind up of a general failure. On the whole he advises physicians to refrain from discussing sexual matters as in nothing else does suggestion work so rapidly and with such serious consequences as here. Worry and disappointment are the essential causes of psychic depression, and psychologic treatment with patience and sympathy brings a rich harvest of success.

149 **Resection of the Knee.**—Riedl gives an illustrated description of extracapsular removal of the knee joint as he has applied it to seven men and four women between 19 and 60. Fixation with horn pegs gave the best results, they healed in place without reaction. He generally used three, from 7.5 to 10 cm long and 0.4 to 1 cm thick.

152 **The Secondary Rays in Roentgen Therapy.**—Schwarz exposed peas to the Roentgen rays, five peas in each of four watch glasses. Two of the glasses were filled with water, the other two with water containing a little of a silver salt solution, and they were all exposed to the Roentgen rays for thirty minutes. The peas were then planted and the growth of the seedlings showed that the secondary rays generated by the silver solution in the water had enhanced the action of the Roentgen rays so that growth was much inhibited.

154 **Blood from Umbilical Vein Can Be Used for Wassermann Test under Certain Restrictions.**—Krukenberg tested by the Wassermann technic the retroplacental blood, blood from the umbilical vein and blood from the mother's arm in 121 normal and eighty two pathologic maternity cases. He found that the retroplacental blood is liable to give a positive Wassermann reaction even when syphilis is entirely out of the question, hence it cannot be used as a test for syphilis. The umbilical vein blood on the other hand gave a positive response only in case of inherited syphilis. A negative response, however, does not exclude syphilis acquired during birth, and does not positively exclude latent inherited syphilis. The blood from the umbilical vein will thus be found useful for diagnosis of inherited syphilis in connection, possibly, with the test applied to blood from a vein in the mother's arm.

156 **Breast Feeding of the Newly Born.**—Jaschke states that years of experience have demonstrated that new born infants thrive better and continue to thrive better when they were suckled at first with colostrum rather than with perfect breast milk. He tabulates findings which show that the nitrogen balance kept positive in spite of the physiologic loss of weight after birth. This testified that the child was getting nourishment, and the very nourishment it needed as more minerals are retained than when it is getting complete breast milk. He also reports excellent results from applying to the breasts a Bier vacuum suction glass as if for stasis hyperemia treatment. This hastens and promotes secretion in the mammary glands so that very few women are incapable of nursing their infants. Where this is the case he tries to secure enough breast milk elsewhere to supply the lack. An unsuspected deficiency in the amount of milk secreted explains many cases of malnutrition in young infants. At the same time, he emphasizes, overfeeding during the first two or three weeks of life is far more harmful for the infant than a slight degree of undernourishment.

159 **Sepsis and Pyemia.**—Nacke says that he has never had a case of actual puerperal sepsis terminate in recovery, the prognosis with puerperal pyemia is more favorable. If the patient is otherwise healthy there is hope of keeping her strength up with careful protein diet, wine and other analeptics until her body is able to rouse and triumph over the infection. Sepsis is more liable to follow forceps, version or a cutting obstetric operation, the fever starts the second or third day and the patient feels much depressed. The fever does not develop with pyemia as a rule until the fifth to seventh day, and between the chills the patient feels comparatively well and eats with appetite. The pulse with sepsis is rapid, galloping, there are signs of peritonitis and the patient feels apathetic and persistently very ill. With pyemia the chills pile up but there are no signs of peritonitis and between the chills the patient brightens up. The prognosis of pyemia grows better as the time passes, he had a patient recover after eighty four chills in the course of thirteen weeks. Another died the forty second day after fifty four chills.

164 **The Declining Birth-Rate.**—Schaeffer's statistical study is based on 7,271 gynecologic cases in the last fifteen years and it brings out the fact that the decline in the birth rate affects only the large families. Not the *Kinder bekommen*, he says, but only the *Viel Kinder bekommen* has fallen off. His statistics also contradict the assumption that the number of abortions has increased in the last decade. The declining

birth-rate is shown to be due to intentional prevention of conception and mainly in families already blessed with children. The only means to arrest the declining birth-rate therefore is to render it easier and less expensive for families to bring up children. As the state is vitally interested in having the population increase, the government should take measures to promote this.

165. **Meningitis Following Spinal Anesthesia.**—Senge reports from Kehrer's service at Dresden the case of a woman of 58 who developed acute meningitis and hemorrhagic encephalitis seven hours after an operation for old prolapse of the uterus, done under spinal anesthesia. She died the thirty-seventh hour and a peculiar spore-forming bacillus was cultivated from the cerebrospinal fluid, viable after lying in boiling water for fifteen or eighteen hours and in a 5 per cent. phenol solution for seventy-five days and in 1 per thousand mercuric chlorid solution for over twenty-seven. He has compiled seven cases from the literature of infectious meningitis following spinal anesthesia, with two deaths, and states that the actual number of cases is probably much larger.

166. **Contracted Pelvis.**—Cuny states that the mortality in von Herff's service was 0.4 per cent. among the 1,368 cases since 1902; omitting the five cases of fatal rupture of the uterus, the mortality was only 0.28 per cent. The principle followed is to ensure a spontaneous, i. e., non-operative delivery, a spontaneous premature delivery, which was accomplished in 88.7 per cent. of all the cases as Cuny describes in detail.

167. **Fatalities after Gynecologic Operations.**—Cancer was responsible for over 42 per cent. of the 163 fatalities in von Herff's gynecologic service at Basel and heart failure in 17.2 per cent. Among the lessons taught by the material presented is the necessity for an earlier diagnosis of extra-uterine pregnancy; the necessity for scrupulous care of the mouth on the part of the operators and nurses; avoidance of speaking during an operation; recognition of the danger of infection from the air and of the importance of means to ward off thrombosis—exercise of the breathing muscles and limbs while still in bed—and copious ingestion of lemonade.

171. **Pregnancy in Art.**—Stratz gives a number of illustrations of various paintings and other works of art depicting pregnant women. The earliest example is a prehistoric outline drawing on a reindeer horn, dating from the stone age, and depicting true to nature a woman in advanced pregnancy. In Japanese art, pregnancy is frequently portrayed, but in classic art Stratz insists that the naked pregnant woman was portrayed only by accident, not intentionally. The gynecologist, however, recognizes in some of the famous paintings of Rembrandt, Titian and Giorgione that their models must have been in the third to seventh month of a pregnancy.

173. **Influence of Flat Shape of the Pelvis on Delivery with Normal Presentation.**—Esch has compiled statistics from several maternities in regard to 3,647 cases of delivery with flat pelvis and normal presentation, and has drawn a curve which instructively shows the chances for safe delivery with conjugate diameter of from 7 to 9.8 cm. Between 9.6 and 10 cm., 94.8 per cent. of the children of primiparae were delivered spontaneously and lived and 97 per cent. of the pluriparae. With a diameter of 8.6 to 9.5 cm. the figures are respectively 91.8 and 90.4 per cent.; with diameter of 7.6 to 8.5, 75 6 and 74 per cent.; with diameter of 6.5 to 7.5 cm., 14.9 per cent.

175. **Effect of Sun's Rays on the Leukocyte Count.**—Aschenheim subjected thirty-one patients to a blood count before and after an hour's exposure of the body to the direct action of sunlight. In 80 per cent. of the cases there was a *general leukocytosis in the peripheral blood with a relative* increase in lymphocytes and decrease in polymorphonuclears. Lymphocytosis is regarded by many authors as a defense reaction against tuberculosis, and Aschenheim suggests that this may account for the favorable effect of sunlight on tuberculosis.

183. **Urobilin in the Stools.**—The research reported suggests that the determination of the urobilin in the stool may have diagnostic import. In thirty-four patients whose metabolic findings are tabulated, the proportion of urobilin in the stools—the average in the daily output taken from several examinations—ranged from 4 gm., in a case of hemolytic jaundice, to 0.012 gm. in a case of cancer anemia. The average in health was 0.13 gm. and this figure was remarkably constant in all the normal persons examined. The limits of the alimentary appearance of urobilin in the urine and stool must be determined first.

184. **Intestinal Auto-Intoxication.**—Eppinger and Guttmann have become convinced from the results of their study of the subject, that substances may be sent out from the intestines to act in the capacity of hormones. If this assumption is confirmed, then the intestines must play a rôle in the body similar to that of the glands with an internal secretion. Histamin, putrescin, cadaverin and tyramin may have a hormone function. They were able to isolate from stool another base, beta-imidazolylethylamin, extraordinarily toxic. If one or two drops of a 1 per thousand solution of this are dropped on a superficial needle-scratch, typical urticaria develops at the spot in less than five minutes. On the basis of this and other experiences related, urticaria patients were put on a diet as free from protein as possible to avoid production of this base, and a marked improvement was noted in several cases. Mellany and Twost have recently announced the discovery of a bacterium which elaborates imidazolylethylamin out of histidin in an alkaline medium. The addition of salt or sugar checks this.

185. **Glycosuria in Pregnancy.**—The glycosuria in pregnancy is generally due to an extra sensitiveness on the part of the kidneys to the sugar in the blood. Nothing is found to indicate any disturbance in the metabolism of sugar, and neither the spontaneous nor the alimentary glycosuria can be accepted as necessarily a sign of pathologic conditions in the kidneys. These statements are based on the metabolic findings in sixteen women during and following a pregnancy. In contrast to these are tabulated the findings in three pregnant women with mild diabetes. The pregnancy had an unmistakably aggravating effect on the constitutional disease. The first patient was a vi-para of 31 who had given birth only

to still born children At the eighth month a course of dieting excluding carbohydrates was commenced and the sugar speedily disappeared from the urine but coma developed at once, which was rapidly fatal The fetus was macerated The second patient, a woman of 25, had had no symptoms to call attention to her mild diabetes until the seventh month of her first pregnancy when she suddenly felt sick, with pain in the stomach region and difficulty in breathing, coma developing the third day Artificial delivery of a macerated fetus did not avert the fatal outcome The third diabetic patient aborted at the second month and recovered The fetus generally dies sooner or later or is constitutionally inferior if it reaches term when the woman has diabetes even in a mild form, so that the question of inducing early abortion should be considered in such cases The aim in dieting should be to reduce the glycosuria within bounds without acidosis rather than to try to banish the sugar altogether

187 **Levulose Test of Liver Functioning**—Schirokauer examined the blood, as well as the urine, in applying the alimentary levulose test, and found that this gives much better oversight of conditions, but he declares that levulose is not very well adapted for the purpose Possibly simultaneous tests of the tolerance for both galactose and levulose may throw more light, investigating the alimentary proportion in the blood In twenty three cases the findings were conflicting with the levulose test, with extreme alimentary levulosemia in some cases there was no levulosuria and vice versa.

190 **Pregnancy Glycosuria**—Mann asserts that the kidneys become hypersensitive to the sugar in the blood during pregnancy even when the proportion of sugar is normal or only slightly above The amounts of sugar eliminated by the kidneys rise and fall with the intake of sugar

193 *Hemorrhage from the Kidney in Hemophiliacs (Nieren blutungen bei Hamophilen) O Mankiewicz
194 Roentgenogram of Tuberculous Focus in Kidney Mistaken for Calculus (Fall von irrtumlicher Deutung eines Nieren rontgenogramms) A W Wischnewsky

193 **Hematuria in a Hemophiliac**—Mankiewicz's two patients were young men who had a history of serious hemophiliac hemorrhages in previous years; in both the hematuria came on a few hours or two days after a steam bath with massage or a superheated air bath The urine filtered without leaving any sediment, so that there must have been hemolysis as well One patient was quieted with morphin and the tendency to hematuria subsided under gelatin internally, ergot, epinephrin and castor oil This patient died suddenly a few months later from acute heart failure The hematuria kept up in the other patient notwithstanding the usual measures, including subcutaneous injection of horse serum Then, at a consultation, Kussmaul's old experience was recalled He failed constantly on account of hemorrhage, in some experiments on dogs, until he kept the dogs from drinking, feeding them abundantly but giving them little if any water On this dry diet the blood became so much thicker that there was no further tendency to hemorrhage Mankiewicz acted on this suggestion in this rebellious case of hematuria, and the hematuria ceased as the patient refrained from fluids He had the heroism to refrain for two weeks from drinking, and his food was prepared as dry as possible The blood and organic juices thus became more concentrated, and contained proportionately more coagulable substance The result was complete subsidence of the manifestations of hemophilia No record of the use of a dry diet in management of hemophilia is known to Mankiewicz, but he has found a reference in Leyden's works to his success in arresting a tendency to hemorrhage from the lungs, stomach or uterus by restricting the intake of fluids, and he added that he had found this a useful measure also in controlling habitual vomiting and diarrhea

Mankiewicz says that on two occasions he had all in readiness to apply transfusion according to the technic described by Elsberg in THE JOURNAL, March 13, 1909, p 887, but each time the hematuria let up under the gelatin by the mouth and restriction of fluids The young man has kept up the gelatin by the mouth to date, it was given by subcutaneous injections during the first four weeks The success in this case justifies the systematic, protracted administration of gelatin in connection with a dry diet as the routine treatment for severe uncontrollable hemorrhage in general, and particularly when the patient is a "bleeder" Even the simple technic for transfusion may prove a dangerous operation in a hemophiliac The literature on hemorrhage from the kidney without appreciable local disease is reviewed

198 *Laceration of Semilunar Cartilage (Zur Diagnose der Menis cusluxation und des Meniscusabrisses) E Bircher

197 **Flap of Fat Tissue to Arrest Sheet Hemorrhage**—Hulse comments on the dangers and drawbacks of using a flap of omentum, fascia or muscle tissue to apply to a bleeding surface in an abdominal operation There is liable to be hemorrhage in the stomach when a piece of omentum is resected, and the bleeding may be threatening in character To obtain fascia or muscle for the purpose requires another operation or, if taken from the abdominal wall, this is liable to injure the firmness of the wall On the other hand, a piece of adipose tissue can be spared from the abdominal wall without harm while it seems to have special advantages for hemostasis, promptly arresting the hemorrhage over a large area after resection of part of the liver, spleen or kidney in nineteen rabbits, three dogs and in two clinical cases In the clinical cases the liver had to be resected in removing a cancer in the gall bladder, and in both cases the sheet hemorrhage from the liver cut surface stopped in a minute or two when the piece of fat was fitted over the bleeding area In only a few of the animals did the hemorrhage keep up until the flap was sutured to hold it in place

198 **Diagnosis of Laceration of Semilunar Cartilage**—Bircher has found that in dubious cases it is possible to ascertain by auscultation of the knees whether the cartilage has been torn It is important to compare the findings in the injured and the sound knee, with the patient in various positions With a rubber ring the stethoscope can be fitted on the uneven surface of the joint

202 Technic for and [illegible] oentgen Exposures (Das Problem [illegible] in der gynakologischen Ront
203 *Resection of Promontory to Correct Contracted Pelvis H Rotter

199 **Early Sign of Extra-Uterine Pregnancy.**—Solowij here reports another case in which his method gave decisive findings The Abderhalden test for pregnancy had given a negative response and the suspicion of extra uterine pregnancy was then given up until the positive response to his sign sustained the assumption of an extra uterine pregnancy, confirmed by operation If the pouch of Douglas is palpated and found normal and then palpation anew, a few hours later, shows a doughy resistance in the pouch of Douglas, all doubt as to the extra uterine pregnancy is at once cleared up He warns that as conditions are changing, the findings are comparatively transient

200. Permeability of Cervical Canal at Close of Pregnancy.—Braude examined 180 primiparae in the ninth or tenth month and found the cervical canal and the os open enough to permit the passage of the finger in 46, and the canal remained open for from five to fifteen days in 20 of the women and from sixteen to twenty-five days in 9. Among 263 primiparae at the eighth or ninth month, the passage was open in 28, including 10 in whom it was permeable for five to fifteen days; 5, from sixteen to twenty-five days; 5, from twenty-six to forty-five days, and 3 from forty-six to sixty-four days. Among 14 at the seventh to eighth months the cervical canal and os were found open in 4 women and they persisted permeable for from seventeen to sixty-five days. The pregnancy in nearly all of the women proceeded to normal term irrespective of whether the passage had been open or not. Permeability of the cervix is thus not a sign of immediately impending delivery.

203. Resection of Promontory to Correct Contracted Pelvis.—Rotter declares that the experiences to date with systematic resection of the promontory to permit normal childbirth by enlarging the diameter of an abnormally narrow pelvis have amply confirmed the simplicity and comparative harmlessness of the method and the excellent and permanent results. It has been applied in nine cases to date. In his case, reported in detail, a woman of 32 had borne eight children but each had died during the difficult labor as the true conjugate measured only 7.8 cm. He sliced off the front of the promontory and the woman had entirely recovered the seventeenth day. Examination five months later showed not a trace of callus; a smooth surface was felt instead of the projection of the promontory, and the diagonal conjugate measured 10.7 cm. against 9.3 cm. before the operation. Schmid's experience with the operation was summarized in these columns, Dec. 6, 1913, p. 2112. Rotter here remarks that Schmid did not do the operation until seven months after Rotter's first publication on the subject, and he thinks that Schmid's claim to share the priority for the operation raises the question as to whether science will accept as valid a seven months' interval for superfecundation of an idea.

204. Murmurs in the Skull.—Köster states that murmurs are audible inside the skull in more conditions than hitherto deemed possible, and they cannot be regarded as pathognomonic of any condition. The murmur heard when there is anemia from any cause may prove instructive as it grows less and less audible as the blood-supply returns to normal. He examined about fifty patients and found the murmurs distinct in a number of cases of hemorrhagic gastric ulcer or cancer, in pernicious anemia and with lesions localized in the skull. He found the murmurs more pronounced with abnormally low hemoglobin content than with low corpuscle count.

223 Postoperative Ileus. G. De Francisco. Commenced in No. 44.

220. The Skin Tuberculin Reaction in Pertussis.—Cozzolino appiled the Pirquet test to 200 children with whooping-cough during a recent epidemic at Cagliari, repeating the test in a few instances. Contrary to what is observed in the acute eruptive diseases such as measles, the skin reaction was not modified by the presence of the pertussis, the findings corresponding to those usual in other conditions outside of the erythematous diseases. Supplementary tests with the Mantoux technic for the intradermal tuberculin reaction confirmed in every respect the findings with the Pirquet technic.

Rivista Ospedaliera, Rome

October 31, III, No. 20, pp. 877-916

224 *Operative Treatment of Cancer of the Colon. R. Bastianelli.

224. Cancer of the Colon.—Bastianelli's article opened the discussion on cancer of the colon at the recent international medical congress at London. He discusses the different indications according as the tumor is in the colon on the right or left side. When ileus is already installed the mortality is high—it was 60 per cent. in 84 cases in the literature since 1900. In 356 cases of cancer of the colon on record in which a single operation was done, the mortality was 33.4 per cent., but in the 44 operated on since 1905 it was only 4.5 per cent. In 68 comparatively recent cases of cancer in the right side the mortality was only 8.8 per cent.—a great change from the 35 per cent. of the total statistics. His compilation includes further 69 cases in which the operation was done at three sittings, with a mortality of 21.7 per cent., and 143 cases in which the Mikulicz-Paul method was applied, with mortality of 2.5 per cent. The mortality of the total 739 cases not complicated with ileus was thus 26 per cent.; but in the last few years it was only 9 per cent. for the right and 15 per cent. for the left side. The patients surviving for more than three years form 29 per cent. of the above. Only 29 per cent. of the total 739 patients have survived for three years or more to date. This is equivalent to the statement that only thirteen are left alive by the end of three years out of every hundred persons with cancer of the colon. Three additional ones drop out from recurrence a year or so later, so that only an average of 10 per cent. are permanently cured by our best technic to date.

INFANT MORTALITY IN THE FIRST FOUR WEEKS OF LIFE

HENRY KOPLIK, M.D.
NEW YORK

Infant mortality in the first four weeks of life is so intimately connected with prenatal influences that we may consider this period of extra-uterine existence as closely allied in many of its aspects to the history of the fetus *in utero*. There are many conditions of the father and the mother which produce an infant unfitted to resist the physical influences of postnatal existence. A large number of infants live but a few hours or days no matter how we strive to maintain life in them. In other words, our present methods of preserving the life of the new-born do not reach such infants. Perhaps it is fortunate that this is so. The children of parents who suffer from organic diseases, such as syphilis, tuberculosis, heart disease, diabetes or nutritional disorders, may be either premature or unfitted to live. Thus we have an immense number of still-births, in some of which the infants succumb to influences not yet fully understood. Parental influence on postnatal life may not yet be an open book to us. We can understand some weaknesses of the father, such as syphilis, pulmonary diseases, general nutritional disorders, etc., but the influence on the part of the father which causes the weakness of the new-born is, in many phases, not as yet clear. Among the working classes and the absolutely poor, lack of proper food, rest and habits react against the fetus and produce a congenitally weak infant.

It will thus be seen, as I understand it, that the subject of infant mortality in the first few weeks of life must deal with certain *definite considerations*:

1. Infants born prematurely and congenitally weak though free from constitutional disease such as syphilis.
2. Infants apparently free from disease but too weak to live—those which fall below a definite standard of living-weight, including all still-births occurring without accidental birth complications.
3. Still-births which result from accidents in delivery or from instrumental interference.
4. Infants who are born of good weight, viable and free from constitutional disease, who die of some acquired infection or condition or of inanition. It may be further shown that the condition of life into which this class of infants is born, that is, whether they are legitimate or illegitimate, is a great factor in the continuance of life, and also, whether they are born in poverty or are surrounded by all the necessities for life is another influence to be fully considered.
5. Infants who are born prematurely, of good weight and viable, but are the subjects of constitutional disease.

We must consider in the first class the infants born prematurely and congenitally weak, those weighing less than 1,000 gm. (2 pounds), as unfitted to live.

In European hospitals premature births constitute from 16 to 20 per cent. of the total number. This depends much on what is considered premature, and those are so regarded which are born weighing less than 2,500 gm. (5 pounds). Deaths among the prematurely born in this country and among those so born in European institutions reach a very high figure. The mortality depends largely on the weight, the mode of management after birth, and whether the new-born has come under *immediate treatment* or has been subjected to exposure. Budin, who made a life-study of this phase of the question, disregards the infant born weighing less than 1,000 gm., for it is rarely reared.

Of infants weighing less than 1,500 gm. (3 pounds), only 1.9 per cent. survive; from 1,500 to 2,000 gm., 2 per cent. survive, giving a gross *mortality of 98 per cent.* for all prematures born weighing from 1,000 to 2,000 gm. The duration of life of premature infants in institutions conducted as Budin did his, is certainly discouraging, and much more hopeless is the problem outside among the poor, where the infant is not taken to an institution. On the other hand, fully 77 per cent. of *the infants born in Budin's institution* whose temperature and strength were conserved and who weighed 2,000 gm. (4 pounds) or less, survived. This illustrates the potent influence of exposure *on the premature.*

As to the further life of the prematurely born infant much depends on the mode of feeding and whether it has escaped extraneous infections. Of those premature infants weighing from 2,000 to 2,500 gm., and born in the institution, 98 per cent. survived. As illustrating the *influence of feeding* Budin cites fifty-four infants discharged from his institution weighing 2,800 to 3,000 gm. Forty-one per cent. of the artificially fed died, as against 15 per cent. of the breast-fed. *We can thus appreciate that aside from the influence of syphilis and constitu*tional disease the premature infant will survive or succumb according to whether the body temperature is conserved, whether it escapes infection, and last, and as important as any, whether it is placed in a position to have artificial or breast-feeding.

In the breast-fed of this class, as in other classes of infants, the mortality is low as compared to the infant artificially fed. Whereas the mortality among prematurely born breast-fed infants is about 15 per cent., that of the *premature infants* on bottle-feeding is 41 per cent. In the classification of infants born at full term, the fact that the breast-fed baby is more resistant to the inroads of disease than the bottle-fed *infant* will be further demonstrated. This does not underestimate the rôle played in the first month of life *of the* other causes of death which are to be considered.

STILL-BIRTHS

Still-born infants are all infants born dead or who have lived only a few hours after birth. These form an immense quota of infants either premature or congenitally weak, with or without constitutional taint, who are either born alive and live a few minutes or hours or are born dead at full term or are living at birth and die shortly afterward from injuries due to accident, as in instrumental or manual interference. The following table taken from Tugendreich, who quotes Prünzing, is interesting as showing clearly the percentage of still-births which have been caused by faulty labor:

Head presentation	1.8
Face presentation	11.4
Breech presentation	20.7
Transverse presentation	31.0
Prolapsed cord	56.3
Placenta praevia	38.3
Induced labor	19.3
Version foot	30.0
Version head	20.0
Breech extraction	18 8
Cesarean section	25.0

Still-births in Germany in 1906 numbered 62,261 of 2,084,738 births and the number has not materially diminished in recent years. This covers, in round numbers, 3 per cent. of all births and 6 per cent. of all deaths.

The statistics obtained by me in New York for the years 1911 and 1912 present a similar condition. In 132,776 births there were 6,749 still-births, or 5 per cent.

The number of deaths from those causes which produce still-births is considerable. On the other hand, the infant born at full term is subject to the dangers of various infections, though of late years these sources of infection have been reduced. Advances in the methods of governing the conditions which surround the parturient woman have considerably reduced the danger of infecting the new-born. Some diseases of the new-born which were formerly prevalent are now uncommon. Malformation and constitutional disease will remain as prevalent in the future as they have been for decades past.

Morbidity among the new-born is of great interest. First and foremost it is noticeable that among breast-fed infants the mortality is not so high as among the bottle-fed; hence, it is seen that though morbidity may be as frequent, resistance to the inroads of disease is much more successful among breast-fed than among bottle-fed infants. Thus of 2,923 infants dying in Berlin of various causes, 373 were breast-fed, the remainder either were bottle-fed, or the method of feeding was not mentioned in the death certificates. Another matter of interest is that of 10,170 deaths in the first year of life, 2,923 occurred in the first month, that is, 28 per cent., and only 7 per cent. occurred in breast-fed infants. (Howarth, Boeckle, Groth, Finklestein, Dietrich, Tugendreich. Moreover, we find that in the heated term, from July to September, deaths among bottle-fed infants outnumber those among the breast-fed as 1 to 4 (Tugendreich). This applies more to infants in the first month of life than to those below one year of age, and proves distinctly that the dangers which threaten the artificially fed infant, such as poverty, heat, ignorance, crowding, unskilful feeding and decomposed food, do not apply in the same degree to the breast-fed infant.

A much-discussed influence on the morbidity of new-born infants or of those below the age of one year, is the social position of the parents. It has been shown time and again that the mode of feeding is not of itself a cause of mortality, except as it is practiced among the poor and ignorant. Among the well-to-do and the intelligent classes the same causes of mortality do not obtain as among the poor, and hence, also, the morbidity of the infant population varies. Krieg and Senteman have shown that under the more favorable conditions of home comforts and surroundings, mortality and morbidity among bottle-fed infants are reduced fully 50 per cent. The social standing of the family affects the mortality of breast-fed infants but little, whereas it is of far-reaching influence among bottle-fed infants. The number of children in the family among the very poor is of some influence. Tugendreich has studied this question in Berlin and found that among the breast-fed infants in families containing six children, the mortality was only one-third as large as that among bottle-fed infants in families containing the same number of children, or 19.8 per cent., as compared to 43.2 per cent.

The question of legitimacy or illegitimacy of the infant is a potent factor, not only as to morbidity, but also as to mortality. The illegitimate infant suffers, as a rule, the disadvantages of poverty, indifference of the parents to its fate and the physical weaknesses with which these infants are well known to be affected. Thus Weinberg shows that the number of still-births among illegitimate infants is fully 1 per cent. higher than among infants born in wedlock. The influence of this condition is found to exert itself in infants below one year of age as a cause of inanition, atrophy, gastro-intestinal disorders, and, therefore, as a cause of mortality.

Before considering in detail the statistics at present available to me in America on infant mortality in the first month of life, it is well to consider the difference between the mortality among such infants in institutions devoted to their care and that among the people at large. I have shown that in Paris the results among the premature are much better as to infants born in institutions than among those brought to the institutions from their homes or places of birth. This is such a self-evident fact that it would seem needless to enlarge on it, yet Budin lays special stress on the increased mortality among the premature who have been subjected to reduction of temperature by exposure, and he also lays stress on feeding as an element in conserving the life of the premature. In institutional work we would expect, to a degree, a marked reduction in septic influences and a reduction of mortality among the new-born which could be traced to this cause, yet we have no statistics on this point. The feeding in maternity institutions, it would seem, should be ideal, and yet from what can be learned, at least in America, this condition is not always present. It is difficult to understand why artificial feeding should be in vogue in maternity hospitals, especially as in these institutions so many women may have an excess of food for their own infants which might be given to those who are not blessed with the maternal breast, yet such a procedure is far from being attempted. The care of the premature, at least in America, has not reached that degree of perfection which our advanced ideas demand. Thus in addition to still-births there is a proportion of deaths in these institutions which are due, as my studies seem to indicate, to avoidable causes. This is true also outside of maternity hospitals.

MORTALITY IN THE NEW-BORN IN THE UNITED STATES

The statistics of infant mortality in the United States, as in other countries, are based on the annual reports of boards of health for infants below the age of one year. None of these reports give us an idea of the mortality during the first four weeks of life, unless specially computed. In a circular letter which I sent to all the boards of health in the United States in 1912, I made inquiry as to the availability of such statistics. It was impossible to obtain any reliable information, except from two or three sources. I therefore determined to compile the desired statistics from the records of the Board of Health of New York City. In order to do this, every death certificate was inspected, and the diagnosis as to cause was obtained from these sources. This was most laborious; at the same time the results were instructive, inasmuch as the actual causes of death were obtained, and our conclusions were drawn from the causes which will be found in the tables. It must be kept in mind that there is a measure of error in this, for not every physician can make a positively correct diagnosis, nor can such diagnosis, even if made by the skilful, be absolutely relied on without a postmortem examination. It should be borne in mind also that the board of health statistics include those of all hospitals, so that the sets of institutional statistics are duplicated in the gross statistics of the city authorities.

For the sake of conciseness, the causes of death in infants under four weeks of age must be grouped. The first great group should include the diseases of the newborn, including the prematurely born; the second, the diseases of the respiratory organs; the third, the diseases of nutrition, which would include marasmus, inanition and disturbances of the stomach and intestine; the fourth, malformations, and finally the various injuries received in delivery.

STATISTICS FOR 1911 AND 1912

The total population at this time, the number of births, still-births, illegitimate births, the number of deaths in infants under one month and the number of deaths in infants under one year, with their relation to the total population for 1911 are recorded in Table 1.

TABLE 1.—BOARD OF HEALTH OF THE CITY OF NEW YORK, BOROUGH OF MANHATTAN

Year	Number of Births	Number of Still-Births	Number of Illeg. Births	Number of Deaths 1 Mo. and Under	Number of Deaths Under One Year	Population
1911	66,537	3,438	1,559	2,732	8,223	2,389,204
1912	66,249	3,311	1,541	2,547	7,675	2,487,796

Of 66,537 births of all kinds, there were 2,732 deaths of infants in the first four weeks of life, or 4.1 per cent. of all births. That is, in round numbers, one infant in every twenty-five, or four in every hundred, died before reaching the age of one month. On its face, this is not so bad a record, until it is compared with the mortality in infants aged under one year. The number of deaths in such infants was 8,223 out of the total number of 66,537 births. Thus fully 33.2 per cent. of the deaths occurred before the first four weeks of life were completed, which is a rather startling record.

The largest number of deaths occurred in premature or congenitally weak infants. This includes also those, who, through unskilful management, died from inanition as a result of incorrect feeding, exposure, etc. There were 1,365 of these deaths, or fully one-half of the total mortality for this age. In 517 death was due to diseases of the respiratory organs, and in 206 to distinct complications occurring in the stomach or intestine, such as diarrhea or gastro-intestinal infection. This latter group must include a number of deaths in infants which belong to the first group of causes, under that of inanition. The next largest number of infants, 517, died of injuries occurring at birth or of sepsis with umbilical hemorrhage or cerebral hemorrhage resulting from instrumental delivery.

In further analyses we find among premature and congenitally weak infants that the highest mortality occurs during June, July, August and September, as a result of gastro-intestinal disease.

Syphilis does not give a large quota of deaths: only 47 in a total of 2,732.

Malformations, including those of the heart, give 131 deaths in the sum total.

In 1912 (Table 3) there were 66,249 births, with 2,547 deaths in infants aged under one month; a slightly lower rate (3.9 per cent.) than that of the previous year. Of these deaths, there were 7,675 in infants under one year. Thus, 34.5 per cent. of the deaths in infants under one year occurred in the first four weeks of life. There was an increase of 100,000 in the population, so that if this is taken into account, the total death-rate will remain about the same, or slightly less, for infants under one year.

Taking up the main groups of causes of death as indicated for the previous year, we find here also a very close correspondence. The total number of deaths occurring in the first four weeks of life being 2,547, the first group includes the premature and congenitally weak and the conditions allied thereto. Fully one-half of the deaths, or 1,388, were caused by these conditions. Respiratory diseases claimed 265 victims; gastro-intestinal diseases and allied infections, 120; malformations, including those of the heart, 156, and injuries, hemorrhages and cerebral hemorrhages, incidental to birth or following the application of forceps, 459. The latter classification in both years does not include still-births.

If we now pass in review the statistics and lessons drawn from a study of infant mortality within the first four weeks of life in a large city of two and a half millions of population, we see, first, that the greatest number of deaths at this time of life are caused by premature birth and lack of strength on the part of the infant to adapt itself to new conditions, but more than anything else the fact is impressive that of this vast number of infants, 5,279, who died within the first month of life, fully 60 per cent. died as a result of neglect, ignorance and the surroundings of poverty, for while prematurity alone may not account for a death, prematurity and exposure will. Many infants adjudged weak are worn out by incorrect feeding and inanition, and could well be saved by care from the moment of birth. This has been shown by Budin, who calculated the mortality in the class of premature infants brought into his hospital, and found the mortality in those from the outside was fully twice as great as among the premature infants born in the wards.

Respiratory diseases claim a large quota, and many of the deaths among these must have been brought about by neglect, filth and ignorance. Aside from still-births, which are quoted by these statistics in a separate class, we cannot help being startled by the large number of deaths which are peculiar to the conditions of birth, such as umbilical hemorrhage (sepsis); atelectasis, due either to faulty care after delivery or to premature birth; injury by forceps, in which the infants die some time after birth, and finally cerebral hemorrhage, which is generally due to instrumental delivery. Fully 936 out of 5,279 deaths of infants in New York City during 1911 and 1912 were the result of some accident or instrumental injury at birth; or, one in every five deaths is directly traceable to the conditions of delivery.

This should make us pause and wonder whether the average physician outside of institutions has attained the skill that he should be expected to have at the present day. This is so delicate a subject that it demands a more thorough report of each birth before any conclusion can be reached.

I have remarked that in preparing this article I wrote to every state board of health in the United States for statistics as to the mortality of infants under one month of age. The replies showed that with few exceptions no such statistics were available, and that in their statistics all boards of health disregarded this period. I received, however, detailed sets of tables with remarks on infant mortality in the first four weeks of life from the state board of health of Michigan. These statistics are of such great interest that I quote them in full The total infant mortality in the first four weeks of life for the years 1910, 1911 and 1912, the cause and the number of deaths from each cause for the first, second, third and fourth week of life, are shown. One hundred and thirty-three causes of death are given

During the year 1910 there were 3,161 deaths of infants aged 1 to 4 weeks. The number of deaths of infants aged 7 days or under was 2,329, or 73.7 per cent; 428, or 13.5 per cent., died during the second week of life; 245, or 7.8 per cent, died during the fourth week of life. The most important cause of death during the year, or the cause of the largest number of deaths, was "premature birth." From this cause, 829 infants died during their first week of life; 44 during the second; 13 during the third, and 7 during the fourth. The cause of the next largest number of deaths was "inanition." One hundred and ninety-two deaths from this cause occurred during the first week of life, 60 during the second; 31 during the third, and 26 during the fourth. The cause of death next in numerical importance was "convulsions," 217 for the year; then follow "enteritis," 111; "congenital debility," 123, "malnutrition," 103, "marasmus," 90; "pneumonia," 88, "organic heart trouble," 76, etc Of important diseases requiring sanitary precautions, there were 4 deaths caused by tuberculosis, 3 by diphtheria and croup; 1 by scarlet fever; 8 by whooping-cough; 88 by pneumonia Twenty-three deaths were from violence, and 70 infants died from injuries received during birth.

For the year 1911 there were 3,228 deaths of infants aged 4 weeks or less, 71 9 per cent., or 2,320. aged 7 days or under; 13 5 per cent., or 436, during the second week of life: 8 9 per cent during the third week of life. and 5 7 per cent., or 185, during the fourth week of life.

For the year 1912 there were 3,262 deaths of infants aged four weeks and under; 2,389 during the first week; 425 during the second, 253 during the third, and 195 during the fourth week of life.

TABLE 2—DEATH OF BABIES AGED ONE MONTH AND UNDER FOR THE YEAR 1911, IN THE BOROUGH OF MANHATTAN, NEW YORK

Cause of Death	Jan April	May	June	July	August	Sept	Oct	Nov	Dec	Totals

Cause unknown	0	0	0	1	0	0	0	0	0	1
										2 732

As in 1911, "premature births" caused the largest number of deaths, 930 in 1911, and 1,125 during 1912.

The table shows that the excessive mortality during the first week is almost entirely caused by premature birth, congenital malformation and feeble vitality. Over four-fifths of the deaths in the first week were recorded as from these causes.

"Some of the causes of infantile mortality are common to every locality, such as prematurity of birth and congenital defects. The health conditions under which the mother lives have an undoubted influence on the vitality of her progeny, and on the occurrence of premature birth. Hereditary influences, such as syphilis, or the degradation and drunkenness of parents, are also of importance. The inexperience with and neglect of their infants by mothers is a most important factor in infantile mortality. Long hours of service of mothers among the industrial classes under improper conditions also is most serious in effect. As regards inexperience, it has been suggested that the deaths of first-born children should be separated from the general infantile mortality. Such returns would undoubtedly show that the rate of death in the first-born is higher than that in the other children; but some of the excess might be attributed to greater difficulty in parturition as well as to parental inexperience. Improper food and methods of feeding are responsible for a large amount of mortality in infants. When improper feeding is a chief factor in producing infantile mortality, a large proportion of the deaths are caused by diarrhea and digestive disturbances. Convulsions are a common result from the irritation produced by improper food."

The points of greatest interest are that the first week of life shows the greatest mortality, the number of infants dying being 71 per cent. to 73 per cent. of the whole number of deaths in the first four weeks. The second week shows a mortality of 13.5 per cent. up to 8 per cent. during the third week, and 5 per cent. to 7.8 per cent. during the fourth week of life. In the main these statistics confirm the conditions causing death as shown in statistics drawn from large numbers of population, in that the causes of the greatest number of deaths are prematurity, inanition, birth injuries, respiratory diseases and diseases of the gastro-intestinal tract. It can thus be seen that for large communities the statistical showing of the causes and number of deaths at the time of life we are discussing remains constant, and the causes are, at least in America, also constant. If this is true of all localities, it would seem that measures to reduce the infant mortality might well be uniformly promulgated, and yet how this is to be done is one of the most difficult problems to be considered at present.

TABLE 3.—DEATH OF BABIES ONE MONTH AND UNDER ONE MONTH OF AGE FOR THE YEAR 1912. BOARD OF HEALTH OF NEW YORK, BOROUGH OF MANHATTAN

Cause of Death	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total

The measures taken toward the prevention of prematurity must consider furthering the strength as well as the health of the mothers. If the mother is given rest, good food and quiet surroundings the child will benefit. Pinard, observing women in France who worked up to the time of their confinement and women who had rest and care for days or weeks before confinement, proved that in the latter the child was benefited and weighed more at birth. Ballantyne in his work on "Antenatal Pathology and Hygiene," has advocated the establishment of homes or retreats where mothers about to be confined might be treated by hygienic methods and aided by pertinent suggestions in order to avoid the evil consequences to the fetus from opposite conditions.

There is a tendency here in America to give more and more attention to the antenatal aspect of infant mortality by the establishment of retreats for pregnant women on lines similar to those suggested by Ballantyne. No measures will be complete which do not also take into consideration the treatment of both parents for any constitutional disease, such as syphilis, which may be co-existent at the time of pregnancy. Good food, surroundings and teaching the duties of motherhood to those who are to see their first-born, will do much to reduce the mortality of this period.

Of deaths resulting from inanition, marasmus or infantile diarrheas, none can gainsay that these infants die not so much as a result of any form of feeding, especially artificial feeding, as on account of the widespread ignorance and even indifference in carrying out the methods of artificial feeding. I certainly believe that among the better situated, where nurses and intelligence can be placed at the disposal of even the premature infants, the results of artificial feeding are not by any means discouraging. With the infant at full term, I feel that from a sociologic point of view artificial feeding by a well-taught mother or nurse is even preferable to a wet-nurse. Wet-nursing as a rule means the death of the child of such a nurse; thus one is sacrificed who has by nature the right to the breast.

The propaganda for the care of the premature and the methods for conserving its strength has not reached that point, at least in America, which would encourage us to hope for better results than we now obtain. The education of the public and the physician on this subject is still to be accomplished. As previously remarked, but few maternity institutions give this subject and even that of feeding the attention it should receive. The question of infant-feeding, the encouragement of maternal nursing, and the education of the general public in methods of feeding is a problem of to-day and much has been accomplished, although much more remains to be done. Social service, milk-stations, lectures to mothers, all will in time tend to reduce this cause of infant mortality.

I have intimated that the perfection of our methods in delivery of the infant and the wide-spread adoption of methods of asepsis in institutions and among the laity have tended to reduce mortality from this cause. At the same time when we contemplate the large number of deaths consequent on operative interference during labor, it is to be feared that there is still much to be accomplished through the instruction of the physician in this direction. I feel also that many of the deaths due to diseases of the respiratory organs could well have been prevented by attention to detail in the care of the newborn.

30 East Sixty-Second Street.

Strenuous Athletics and the Heart.—The hypertrophied heart is more liable to acute cardiac dilatation than the normal heart. At the state university, during the past two years, there have been four cases of acute dilatation in athletes and only one in the non-athletes, although relatively few students take part in the major college sports. In case of severe fever these large hearts seem to be especially vulnerable. In the graduates from Annapolis it has been found that there are six times as many deaths from heart-disease among athletes as among non-athletes. If physical training is to be made compulsory in our schools and violent athletic contests are to be incited by crowds and publicity, a serious duty devolves on the medical profession to study the results carefully and, in case of each individual youth, to supply that balanced judgment concerning the value of various kinds of physical exercise which only those can have who follow human life from the womb to the winding-sheet.—C. R. Bardeen, M.D., *Wisconsin Med. Jour.*

AN EPIDEMIC OF SMALL-POX IN SONORA, MEXICO

LLOYD MILLS, M.D.
LOS ANGELES

A paper based on practical experience with small-pox and giving further striking evidence of the remarkable protective value of vaccination is never untimely. This is especially true in these days when common ignorance of the disgusting horror of the ravages of small-pox has caused so much ill-advised and even fanatical opposition to the one essential weapon against it, vaccination.

This paper is also timely in that it offers some corollaries on frequent Mexican medical abuses, the results of which may be brought forcibly to our notice in case of intervention by our country in the internal affairs of Mexico.

In October, 1912, I was in the Yaqui Valley, Sonora, engaged in making a climatic and hygienic survey of the region for a large irrigation project.

In the spring of 1912 small-pox had become epidemic in a group of towns about eighty miles to our south, but the spread had been partly limited by the habit of sleeping outdoors during the hot weather. With the cooler autumn evening the families began to herd together within their adobe huts, and because of this closer contact the epidemic renewed itself fiercely. No organized vaccination had ever been done in this region, and small-pox had always been present. No epidemic of magnitude had occurred, however, for a number of years, and the entire youth of the community offered rich virgin material for the loathsome invasion which now began. When this reached the point at which many new cases were appearing daily and deaths were frequent, a general exodus took place from these towns, spreading the disease freely in all directions, for no quarantine was attempted. After hundreds of deaths had occurred, one or two incompetent Mexican physicians in the government employ were put in charge of the situation, but did nothing to limit the contagion.

There are five pueblos in the valley lands of the Yaqui River with populations of from one to three thousand. These pueblos are named Cocorit, Bacum, Torin, Potam and Vicam. The contagion first entered the valley at the pueblo of Cocorit by means of a family which came by rail from the heart of the infected district. Before the local authorities became alarmed, about sixteen cases were scattered throughout the town, and then an incompetent French physician in the government service was placed in charge. When not intoxicated he was devising means of grafting from the town and state in collusion with the mayor and the mayor's secretary. Absurd charges were made for office rental, carriage hire and medicines. Fictitious expense accounts were created for food-supplies for whole families, and for several weeks all that was actually done toward limiting the epidemic was an infrequent visit to some of the infected homes, where spirits of camphor was given the unaffected members of the family to rub on their hands, face and clothing.

During all this time there was the freest of intercourse between the patients and all their relatives and friends, members of families with sick went freely to the church, the stores and to their usual meeting-places, and of course hygienic conditions were primitive in the extreme. Consequently the incidence of the disease rose steadily until there was a daily average of about forty cases of active small-pox and a daily death-rate of from five to twelve cases.[1]

The high mortality finally forced the authorities to a show of greater activity, so a large supply of vaccine points was procured, the date of the expiration of the vaccine being June, 1912, a date then about eight months past. Of the several hundred persons who applied for vaccination about half a dozen were successfully vaccinated, although, as I found later, about 92 per cent. of this town of nearly three thousand people, had never been vaccinated and had not had small-pox.

Finally the epidemic began to have a commercial phase, for the large outlying Mexican ranches began to suffer severely. On the large hacienda owned by one Jesus Parada, over 80 per cent. of the workmen and their families died.

At the outset of the epidemic I had thoroughly vaccinated the employees of the irrigation project itself and of the near-by American ranches (about a thousand in all), and in this well-vaccinated group but four mild cases appeared. This contrast was so obvious and amazing to the Mexican ranchers that when, to prevent United States quarantine against the region, I volunteered to rid the entire township of the pest within thirty days, without charge for my service, and asking from the town only the cost price of the necessary fresh vaccine and of the few simple disinfectants and remedies, the few of the ranchers who dared brave the wrath of the local cabal went over its head to the governor. To the Mexican mind it was incomprehensible that anybody could volunteer to do gratis any service involving intense personal activity, loss of time and considerable personal danger from disease and violence. They reasoned that some at present hidden means of extracting money would surely come to light, and it was only after repeated letters to and interviews with the government that my appointment as sanitary delegate was made.

While waiting for my vaccine,[2] I arbitrarily divided the town into quarters and had a careful census taken, with the number of persons in each family clearly indicated.

Then began a house-to-house vaccination in which each person from this census list had to be accounted for at once. Everybody was vaccinated, regardless of pockmarks or old vaccination scars, and vaccination was repeated once if unsuccessful the first time. Among the Yaqui Indians, who believe that one should take small-pox as the ordinary Mexican takes a bath, a trying procedure which must be done here once in a lifetime, there was some sharp opposition. This was aggravated by the report, traced later to the mayor, that it was my intention to kill their children. Because of this I twice narrowly escaped being stabbed, a watchful guard averting the first attack, and once I turned intuitively while vaccinating a Yaqui infant, to find the father almost on me with his knife. After being disarmed, he was vaccinated.

At the end of nine days this universal vaccination was completed, my days beginning at daybreak and lasting far into the starlight.

When the census was made 102 active cases were found in the town. Four days later when I began vaccination there were 127 active cases, and the high tide of 156 active cases was reached on the third day of vaccination. The last case of small-pox contracted within the town appeared five days after ending the vaccination, or just two weeks after the beginning of my attack on the contagion. At the time of writing this paper, Nov. 8, 1913, this well-vaccinated pueblo remains entirely free from the disease, although the surrounding pueblos without exception are being decimated. Cases have been imported, but no case has since occurred among the native resident population.

The military town of Torin, with its staff of Mexican army doctors and its constantly changing bodies of troops, suffered worst of all the pueblos. It established no quarantine, no vaccination was done, and at present the disease is running an unchecked and virulent course, which will probably continue until it has exhausted the human material. One resident stated to me that "everybody has had or is having small-pox, even to the horses."

This paper is not intended as a clinical study of small-pox. The stress of the single-handed labor was too intense to permit of anything but general impressions, except in the matter of observation of the types of disease and of data relative to the effect of vaccination, which data I was most careful to keep.

In the town of Cocorit, during the two weeks of my active campaign, there were 229 cases of small-pox with 82 deaths, a mortality of 31 per cent.; 71 of the deaths were due to purpuric small-pox between the fourth and seventh day after onset of the symptoms. Nearly all of these patients had an intense diffuse bronchitis, extensive ulcerations of the pharynx and soft palate and greatly swollen tongues. Six died from confluent small-pox. Two deaths occurred from bronchopneumonia, one from purulent inflammation of the knees, ankles, elbows and wrists with death from septicemia and two from abortion during the disease, the fetuses having no eruption.

In this town I vaccinated 2,878 persons, of which number about 5 per cent. had marks of early vaccination, and about 3 per cent. more or less distinct pockmarks. One man of 72, who had had small-pox over fifty years previously, and on whom the pocks showed clearly, was successfully vaccinated, and two other elderly people so marked, reacted, though very moderately. The group of 144 previously vaccinated persons had an average vaccination period six years past. Patients with strongly marked scars were seldom successfully revaccinated, though there were several exceptions to this. Of the total number, less than 25 per cent. were successfully revaccinated, and but two of the whole group contracted small-pox. One, a child, successfully vaccinated three months previously, died of confluent small-pox. The other recovered after a very mild attack.

Out of the entire pueblo forty-eight persons who developed small-pox were vaccinated during their stage of incubation. Thirty-nine of them recovered from mild attacks of discrete small-pox. Two recovered after severe attacks of combined vaccinia and confluent small-pox; one died of confluent small-pox and vaccinia; one died of purpuric small-pox and five died of combined purpuric small-pox and vaccinia, the vaccine having been administered too late in the last seven cases. Most of the pueblo had been exposed and numerous other persons must have been vaccinated during the first few days of the incubation period of the disease, and must have been protected from small-pox by the development of the vaccinia.

In over 80 per cent. of the 2,878 cases vaccination was successful at the first visit. Excluding the cases of previous small-pox and previous successful vaccination, less than 1 per cent. of the remainder resisted revaccination.

---

[1] There was no way of obtaining accurate details of the situation at this time, for surreptitious burial was the rule and the vital statistics of Mexican towns are notoriously incorrect; hence these figures are approximate.

[2] I used only vaccine lymph in capillary tubes made by a Berkeley laboratory, for I had found vaccine points to be far less certain.

Altogether, during this experience I vaccinated over five thousand persons, practically all of whom I saw subsequently. Only rarely was a protective dressing used over the vaccination site, for I had neither sufficient time nor materials for dressings during most of this intense work. Yet even amid the reeking filth of Mexican home life there were complications following vaccination in but eighteen cases. In thirteen of these, deep ulcers developed at the site of inoculation; a baby scratched the pustule and received multiple inoculations; there were three cases of deep abscess formation and one Indian child died of tetanus following the attempts of its mother to rid the arm of vaccine by plastering it with foul mud of the village street.

This experience is remarkable because it offers so exact and specific an example of the value of vaccination, unaided by any other means, in limiting a fairly virulent epidemic of small-pox. Between the time of the onset of the disease in the pueblo and the finish of the vaccination approximately 15 per cent. of the original population must have been affected. Considering the rapid progress which the epidemic was making, as shown by the number of cases already in the incubation stage at the time of vaccination, it is reasonable to assume that practically the entire unvaccinated part of the population would have contracted the contagion eventually, just as occurred in all the adjacent pueblos. Yet within two weeks this epidemic, which had already reached alarming proportions and threatened to become most formidable, was absolutely and permanently eliminated.

UNIVERSAL CIRCUMCISION AS A SANITARY MEASURE

ABRAHAM L. WOLBARST, M.D.
NEW YORK

Of late there has been noticeable a decided tendency on the part of some medical men, mostly pediatricians, to condemn the ancient practice of ritual circumcision. This tendency is amply demonstrated in the statement of the late Professor Maas, and apparently approved by Dr. L. Emmett Holt,[1] that "it is the duty of the physician to raise his protest against the performance of ritualistic circumcision in every case."

When we examine into the reasons underlying this remarkable dictum of Maas, we find that the opposition is based on the possibility of infections being carried to the infant by careless or ignorant operators, to whom the rite of circumcision is sometimes entrusted.

Holt[1] states that after a search through medical literature with the assistance of Drs. Alan Brown and Stafford McLean, he was able to find references or reports of forty cases of circumcision tuberculosis in addition to the case he himself cites. It must therefore be apparent when we consider the millions of Jewish and non-Jewish children who have been subjected to this ritual operation, without untoward incident, that the number of infections with tuberculosis must be rare indeed. The same is true of syphilis, the second disease which is occasionally transmitted through circumcision.

When, however, the opponents condemn the practice of circumcision, *in toto*, because of the possibility of these infections, it seems necessary to point to the other side of the picture; it is, therefore, the purpose of this paper to demonstrate that circumcision, far from being the menace that some of these observers would have us believe, is, on the contrary, a most beneficent practice from the sanitary aspect, and that it should be encouraged in every possible case, whether it be done as a ritual act or as a purely sanitary measure.

It is not my purpose to condone or even seek pardon for the acts of those who, in the performance of ritual circumcision, have spread infection of any kind whatever. These men should be regarded as unfit to practice this act, and should be debarred from performing it. The Jewish Community (Kehillah), representing nearly a million Jewish residents of the city of New York, having been made aware of the occasional infections we are discussing, is even at this moment taking steps to prevent their further occurrence by seeking to place the practice of ritual circumcision on a thoroughly modern basis. It is hoped to accomplish the desired end by the formation of a board of physicians, consisting of well-known physicians and surgeons, who will instruct the "Mohelim"[2] in surgical technic, particularly the principles of asepsis, hemostasis and general hygiene. In this way, only those who have satisfied the board of physicians of their knowledge and practice of the rules of asepsis will receive the moral sanction of the Jewish Community to perform the ritual, and thus the unfit or ignorant will be weeded out.

In fact, the Mohelim themselves have asked for such supervision and instruction. Rev. Dr. J. L. Magnes,[3] president of the Kehillah (Jewish Community), says:

> The Kehillah was approached by the Society of Mohelim for the purpose of organizing a board of recognized physicians and surgeons to whose authority in hygienic and medical matters the Mohelim were to submit. The plans of the Society of Mohelim include the formation of classes for instruction in hygiene and allied subjects, to the end that a certificate may be issued by the board of physicians and surgeons to such Mohelim as satisfy all requirements. A list of certified Mohelim in the office of the Kehillah placed at the disposal of the community would doubtless surround the rite of circumcision with all necessary safeguards.

It is, therefore, apparent that the men who perform the rite are themselves anxious to avoid any untoward accidents in the performance of this little operation, and are willing to cooperate in weeding out those who are either diseased or ignorant of the primary surgical rules of asepsis. It should be remembered that these men are remarkably skilful, as a rule, in the performance of circumcision, and I venture the opinion that their skill and dexterity in operating on infants are by far greater than that of any surgeon. This is due to their extensive experience and to the fact that they are trained to do nothing else. If, therefore, a few of them perform their duties in disregard of modern principles of asepsis, the criticism should be leveled at them, as individuals, and not at circumcision *per se*. One might just as rationally denounce the operation of laparotomy and protest against its performance, just because towels, artery clamps and other foreign bodies have been left in the abdominal cavity by careless surgeons.

The infections with syphilis and tuberculosis, when they do occur, are caused by these few Mohelim who still adhere to the ancient practice of stopping the bleeding by sucking the edges of the wound. But this practice is merely a relic of ancient times, and most of the modern operators never do it. I am informed by several rabbis and Mohelim that neither the ritual nor the rabbinical law demands that the wound shall be sucked, if another method of hemostasis can be safely employed. In this connection, Rabbi H. Pereira Mendes[4] of New York writes:

---

[1] Holt, L. Emmett: Tuberculosis Acquired through Ritual Circumcision, The Journal A. M. A., July 12, 1913, p. 99.

[2] "Mohelim" is the plural of "Mohel," by whom the rite is performed.

[3] Magnes, J. L.: Fourth Annual Report of the Kehillah (Jewish Community), April, 1913.

> Less than a single century ago, hemostasis by hot oil or hot pitch was countenanced by accepted surgery. It required time to bring about changes to modern methods. Much less time will be required to improve the methods complained of in "ritualistic" circumcision, particularly when we remember not only that many Jewish operators in America use modern methods of asepsis, and that in such countries as England, France, Germany and Scandinavia they may not otherwise practice, but also that the Jewish religious law insists on every precaution in matters of health and demands that when "Sekanah" or "danger" to health is critically involved, any religious custom and any duty not may, but must, be overridden.

I have the assurance of Rabbi Philip Jaches of New York, who has successfully performed more than seven thousand ritual circumcisions, that the ancient practice of sucking the wound is considered obsolete, and that cotton and gauze, wet with antiseptic solutions, are being commonly used for hemostasis.

In view of these facts, I feel justified in saying that the rite of ritualistic circumcision should not be condemned, but rather those who perform it in contravention to the modern rules of asepsis and the spirit of the Jewish law. That these faulty operators are few and gradually disappearing must be evident by the generally increasing demand on the part of parents for modern surgical methods in the performance of the rite.

At present, however, I am principally concerned with the operation of circumcision as a necessary sanitary measure. Not only am I heartily opposed to any curtailment of the practice of ritual circumcision, but I also advocate its universal employment in all male children, whether Jewish or Gentile, from a purely sanitary and health-giving point of view.

My attention was first attracted to this subject some years ago, when I saw the striking difference in the amount of local venereal ulcers treated at the Good Samaritan Dispensary and the Beth Israel Hospital, at which the patients are almost entirely Jewish, as compared with the vastly larger proportion which I saw while working with Chetwood at the Polyclinic Hospital and in my own service at the West Side German Dispensary, at which nearly all the patients are non-Jewish. Not only was the proportion of syphilis and chancroid much less among circumcised patients, but also the general cleanliness of the parts and the absence of serious local complications due to the presence of a foreskin, made a lasting impression on my mind, with the result that universal circumcision is, in my opinion, an absolute necessity, when we consider the general welfare of the race. Specifically, my reasons for advocating universal circumcision are as follows:

1. It is a great aid to cleanliness of the genitals.
2. It is a decided prophylactic against infection with syphilis and chancroid.
3. It prevents in great measure the development of venereal warts, herpes, epithelioma and other growths.
4. It offers a diminished tendency to masturbation, nocturnal pollutions, convulsions and other nervous results of local irritation.
5. It diminishes local complications in the presence of venereal diseases.
6. It makes the "fourth venereal disease" impossible.
7. It prevents the development of phimosis and paraphimosis, with their attendant complications.

Let us consider these items at greater length:

I. AN AID TO GENITAL CLEANLINESS

Surely, any one who has worked in a male clinic must have observed that very few of the uncircumcised, at least among the poor and middle class, pay proper attention to the cleansing of their genitals. Times innumerable, in my experience, the stench arising from the confined and retained balanic secretions has been almost unbearable, even in the absence of any particular disease. Add to this the increased element of inflammation in balanitis associated with any one of the venereal diseases, and the argument for circumcision as a measure of hygiene must be apparent to any but a man deprived of his olfactory sense. Not infrequently adhesions form between the glans and the prepuce; in these cases, retraction is next to impossible and there is a constant accumulation of the secretions, with all that the term conveys. I have encountered hundreds of men who have seldom or never retracted the foreskin for cleansing purposes.

II. AS A PROPHYLACTIC AGAINST SYPHILIS AND CHANCROID

I am a firm believer that men who have been circumcised are less prone to infection with these diseases because of that fact. It is not necessary to go into a discussion of the obvious reasons for this view; suffice it to say that this view is also held by most authorities on venereal infections, as I shall show below. For further substantiation of this belief, I have searched my private records, with more than striking result. The records of 800 patients treated in my office were studied; of these, 400 were circumcised and 400 uncircumcised. In order to determine whether or not the Jewish (circumcised) patients suffered equally with their Christian (uncircumcised) neighbors from syphilis and chancroid (gonorrhea not being considered), I found the interesting data given in the accompanying tabulation.

SYPHILIS AND CHANCROID IN THE CIRCUMCISED AND UNCIRCUMCISED

CIRCUMCISED PATIENTS

Disease	Cases	Per Cent.
Gonorrhea	321	78
Syphilis and chancroid	79	22
Total	400	

UNCIRCUMCISED PATIENTS

Disease	Cases	Per Cent.
Gonorrhea	238	59
Syphilis and chancroid	162	41
Total	400	

It will thus appear that of 400 circumcised patients, 78 per cent. sought treatment for gonorrhea and 22 per cent. for syphilis and chancroid; whereas of the same number of uncircumcised patients, 59 per cent. sought treatment for gonorrhea and 41 per cent. for syphilis and chancroid. The difference must be strikingly convincing. Many years ago Hutchinson observed in the Jews' quarter of London that the proportion of Jews to Christians among the out-patients was as one to three; at the same time, the proportion of cases of syphilis in the former to the latter was one to fifteen.† It has also been pointed out by Hutchinson, Fournier, Clerc and other authorities[5] that the foreskin is the favorite site for about 75 per cent. of primary chancres. These data show conclusively that there is far more syphilis among the uncircumcised than among those who have been circumcised. Nevertheless, it may be charged that figures can be distorted to prove almost any contention. In order, therefore, to forestall this possible criticism of the data just quoted, I have fortunately been able to secure the opinion of professional colleagues in various parts of the country, whose experience in the treatment of diseases peculiar to men has enabled them to determine whether or not their uncircumcised patients were more often infected with syphilis and chancroid than those who had been circumcised. In response to my inquiry, these gentlemen kindly wrote as follows:

---

[4] Mendes, H. Pereira: Correspondence, The Journal A. M. A., Sept. 6, 1913, p. 786.

L. Duncan Bulkley, New York: I have observed a very much larger proportion of syphilis and chancroid among the uncircumcised than in those who have been circumcised.

E. G. Ballenger, Atlanta, Ga.: I regret that I have not statistics which bear directly on this point. The tender, often macerated, condition of the quasimucous membrane of the glans penis and foreskin, especially in the region of the frenum, undoubtedly affords a more favorable site at which organisms may gain entrance than does the hardened skin of the circumcised. The abrasions and so-called "hair cuts" are also more likely to occur in the uncircumcised than in the circumcised. More than 75 per cent. of cancers of the penis are observed when phimosis exists in the uncircumcised. Masturbation appears to be less prevalent in the circumcised.

F. Bierhoff, New York: I would say that although I have not kept any statistics with reference to the relative frequency of syphilis and chancroid among the circumcised and the uncircumcised, I am positive that both of these diseases are more frequently encountered among the latter class. This is particularly true of chancroid.

Charles H. Chetwood, New York: Highly in favor of the operation of circumcision as a sanitary measure.

Hugh Cabot, Boston, Mass.: I have no doubt that these infections are less common in proportion to exposure in the circumcised than in the uncircumcised.

B. C. Corbus, Chicago: You know as well as I do, that for hygienic measures, circumcision should always be advised. In regard to the occurrence of infection in those that are not circumcised as compared with those that are, I am truly unable to draw any definite conclusions. The "fourth disease" is absolutely one infection that cannot exist on an individual who has been properly circumcised. As the infecting organism is anaerobic it must require a closed foreskin for the growth of the organisms.

B. Erdman, Indianapolis: There is a question in my own mind as to the question of circumcision preventing, so to speak, gonorrhea and chancroid. I don't believe the uncircumcised suffer more from these infections than the circumcised, but in syphilis the matter is entirely different. I want to say that in the last thirty-three cases of syphilis, recent infections, having seen the sore from three to eighteen days after appearance (no extragenital lesions considered), twenty-seven were in uncircumcised patients and six were in circumcised (four were Jews). There is no doubt in my mind but that circumcision and plenty of soap and water are valuable in the prevention of lues.

George Henry Fox, New York: Many years ago I noticed in my clinics *that circumcised patients rarely appeared with* local venereal diseases. I still have the impression that the prepuce, in a certain class of patients, predisposes to infection with chancre and chancroid, although I have no data to offer on which a ratio of immunity could be based.

Eugene Fuller, New York: I think very favorably of circumcision as a sanitary and prophylactic measure. I think there is more syphilis and chancroid among the uncircumcised. I cannot state offhand the proportion. The preputial orifice and the mucous surface of the parts removed in all instances of properly performed circumcision are the prevailing seat of venereal sores among the uncircumcised. Abrasions during coitus, without which chancre and chancroid cannot result, occur much less frequently in connection with those properly circumcised than in connection with those who are not. Then again circumcision removes all danger of balanitis. All persons afflicted with balanitis in a severe or chronic grade present a raw surface at all times. Consequently such men can hardly escape being inoculated with a venereal sore in sexual contact with an infected woman.

M. L. Heidingsfeld, Cincinnati: I believe that the uncircumcised is more susceptible to the initial lesion of syphilis and chancroidal infection for the following reasons: Abrasions and macerations, the open door to infection, are more common in the latter for mechanical reasons and lack of cleanliness. Again, I consider the normal unbroken skin the surest protection to exposed infection. Although syphilis and soft chancre infection is by no means of rare occurrence in my circumcised clientele, and possibly equally large, for personal reasons, with that of the uncircumcised, it is evident to me that the circumcised temperamentally are more given to lascivious vice and expose themselves to a greater degree than the uncircumcised.

F. J. Leviseur, New York: Looking back over a large experience of many years, I may state as my belief that the Judaeus Apella is less frequently affected with chancroid. It is not so however, with syphilis. I believe that the latter occurs fully as often in those who have been circumcised as in those who have not, if not oftener.

H. H. Morton, Brooklyn: I am thoroughly in favor of circumcision as a hygienic measure and also as a prophylactic against infection with venereal disease, particularly chancroid and chancre. I have also noted that in the great number of amputations of the penis which I have done for epithelioma of the glans the patients, with but one exception, always had long foreskins.

E. Wood Ruggles, Rochester, N. Y.: Since engaging in private practice here fifteen years ago, I have observed a much smaller proportion of chancres among Hebrew patients, who constitute a rather large part of my clientele, than among Gentiles. As to a definite ratio I cannot state positively, but should say that, roughly speaking, not over a fourth as many cases of penile chancres and chancroids occurred among the circumcised. There can be no doubt that the cleanliness, the *freedom from balanitis and herpes and the toughened condition* of the skin caused by constant friction against the clothing produces a very decided protection against these diseases.

G. K. Swinburne, New York: When I first took my clinic at the Good Samaritan Dispensary in 1889, I had been working in several other clinics. I had also spent six months in Vienna in the clinics there. After I had been working for some time at Essex Street, I noticed that in proportion to the amount of gonorrhea I was treating, I was not getting anything like the proportionate amount of chancroid and syphilis that I saw at Chambers Street, or the Vanderbilt or Presbyterian clinics. This was very noticeable, and I believed it to be due to the fact that the vast majority of my Essex Street patients had been circumcised. Since 1889 I have not had occasion to change my views. I should not wish, however, to attempt to state proportions in figures, suffice it to say that the difference was very striking.

H. J. F. Wallhauser, Newark, N. J.: By far the greater number of initial lesions that have come under my observation were located in the prepuce. I have also several times traced an infection to a preexisting herpes preputialis, and very frequently patients have informed me than an abrasion occurred during coitus which healed rapidly and was followed by the appearance of the initial lesion on the site of the injury. Deducing that the uncircumcised are more susceptible to superficial injuries on account of a mild form of inflamma-

[5] Alexander: Die Hygienische Bedeutung der Beschneidung, Breslau, 1902.

> tion which is nearly always present, especially in men in whom the glans is completely covered, there can be very little doubt as to the greater liability to infection in this class of individuals.
>
> M. W. Ware, New York: I am wholly unbiased in my opinion when I say that circumcision is absolutely no safeguard against any of the venereal diseases that human flesh is heir to and which exist in equally as large a number among the circumcised as those not circumcised. Thus I have seen in twenty years of dispensary and hospital practice a surprisingly large amount of syphilis in its late manifestations (tertiary) among the parent stock of the emigrant Russian Jew, as well as recently acquired syphilis in the sons of the next generation. Perhaps the chancroidal infections are not quite so common, and though your inquiry did not cover gonorrhea, I venture the opinion that the organism of Neisser does not discriminate between the urethras of circumcised or uncircumcised penes. The following personal experience may interest you: Recently the son of orthodox Jews, a graduate of Harvard, whose son I was about to circumcise, told me that he was having the ritual done surgically at least, to appease the irate grandfather (paternal), but forthwith he proceeded to rouse the ire of said grandparent by telling him that circumcision was a relic of barbarism in so far as it signified a sacrifice on the altar of God which called for an offering of lamb's blood, but for which the blood of the new-born male on the tenth day was substituted by the performance of the circumcision. I could cite many more reasons which speak against circumcision from any point of view. In conclusion, I would be quoted as characterizing circumcision as a fetish surviving from ancient times.

To these views may be added the opinion expressed by G. Frank Lydston,[6] Chicago:

> Circumcision is a most commendable practice. Whatever religious views one may hold, it must be conceded that Moses or whoever devised the operation was a hygienist of no mean pretensions. The Jews are social hygienists in many ways, some of which might well be imitated by the Gentiles, but none of their religious customs is quite so sensible as the rite of circumcision. Circumcision promotes cleanliness, prevents disease, and by reducing oversensitiveness of the parts tends to relieve sexual irritability, thus correcting any tendency which may exist to improper manipulations of the genital organs and the consequent acquirement of evil sexual habits, such as masturbation.

I may likewise add the opinion of E. M. Corner,[7] the well-known English surgeon, who is a firm believer in the value of circumcision, as is evidenced by these words:

> For choice, it (circumcision) is an operation which should be done in early babyhood. Then the operation is borne well, giving the minimum of discomfort, no anesthesia is required, and usually no stitches. Up to 6 months of age, a healthy baby is very easily nursed, as it leads, more or less, the life of a vegetable: feeding and sleeping. On the other hand, there is no doubt that many cases of apparent phimosis in babies get well from the natural stretching of the prepuce by erections. In spite of this, I would strongly urge that this little operation, when advisable, is recommended at this age on sanitary and moral grounds; all hypothetic arguments being avoided. . . . Whenever possible, it should be done as early as the child's condition permits.

A careful perusal of the views herein expressed must be convincing, to say the least, of the great value of circumcision as a sanitary measure. Detailed comment on the individual views seems altogether unnecessary. It may be pointed out, however, that there is a practical unanimity on the part of those who have kindly expressed their opinions as regards this question. The one dissenting voice is that of Dr. M. W. Ware, and with all the deference due to my one-time preceptor, I cannot but feel that his opposition to circumcision is based on other than scientific grounds. Even assuming for the moment that his Harvard friend is correct in his weird statement that circumcision was regarded as a substitute for the "sacrifice on the altar of God" (which is not true), I cannot see how that has any bearing on the present-day value of circumcision as a sanitary measure. To close our eyes to the utility of this little operation because it is a relic of ancient times brings to mind the similarly ancient custom of biting one's tongue to spite the nose. If there is any objection to circumcision, it should be based on valid, scientific grounds, and it is to be regretted that so capable an observer as Dr. Ware has not offered any objection more convincing than that "it is a fetish surviving from ancient times."

It must be apparent, however, that the vast preponderance of modern scientific opinion on the subject is strongly in favor of circumcision as a sanitary measure and as a prophylactic against infection with venereal disease. Whatever objections have been raised owing to the improper performance of the operation should not militate against circumcision *per se*, but against those persons who fail to do it properly.

III. AS A PROPHYLACTIC AGAINST VENEREAL WARTS, HERPES AND EPITHELIOMA

There can be no question that the development of venereal warts and herpes is favored by the presence of a foreskin and a chronic balanitis. The instances in which they are seen in a circumcised patient are rare indeed. They are usually found just behind the corona, in conjunction with a more or less irritated foreskin.

The late Jonathan Hutchinson stated as his belief that phimosis and balanitis lead to cancer of the penis. This view is likewise held by innumerable observers who have had the opportunity of studying the relationship between the chronic inflammatory condition existing in the presence of balanitis and the development of this form of cancer. All writers agree that penile cancer in the circumcised is exceedingly rare. I need but recall the remark of Dr. H. H. Morton, previously quoted, to the effect that all but one of the patients in whom he amputated the penis for cancer were blessed with long foreskins. Chetwood, in his latest work,[8] states that the percentage of cancer of the penis "in those of the Hebraic race is strikingly small." One need not stretch the imagination too far, to realize that the constant friction and irritation occasioned by the presence of a foreskin, particularly a tight and long one, may act as an exciting cause of cancer in men predisposed to this disease. Especially is this true of the ignorant and poorer classes, who are not overclean, and who, apparently, are not instructed in their youth by their parents or guardians as to the necessity for an occasional cleansing of the preputial cavity. Barney,[9] basing his observations on a study of one hundred unselected cases of penile epithelioma, concluded that phimosis is preeminently the most important of its exciting causes, occurring in over 85 per cent. of cases. It is worthy of note in this connection that there was not a single Hebrew among the hundred patients, a fact which an editorial writer[10] considers a "most convincing argument in favor of circumcision in an adult whose prepuce cannot be easily and completely retracted." Surely if circumcision is indicated at all, the time to perform it seems to be before the child becomes an adult and runs the risk of cancer.

For the further information of those who regard circumcision as a relic of barbarism without any redeeming value, it is interesting to note that Bashford[11] says:

> Similar conclusions have been arrived at by a consideration of cancer of the penis, which is extremely frequent in some races, and very rare in others living side by side with them. The frequency of cancer of the penis is apparently associated with chronic irritation due to the accumulation of dirt and secretion under the prepuce, whereas it is practically unknown in Mohammedan races who practice circumcision.

IV. AS A PROPHYLACTIC AGAINST MASTURBATION

It is a well-known fact that the foreskin is a frequent factor in the causation of masturbation, not alone in children, but *in adults as well.* This has been amply proved by the fact that circumcision has become recognized as a most effective remedy in these cases. The glans in the uncircumcised is highly sensitive, and this, combined with the constant friction of the prepuce and the accumulation of the secretions, brings on a condition of irritation which is often relieved only by manipulation and scratching, with the result that masturbation becomes more or less of a habit.

A repetition of a paragraph from Lydston (already quoted) may be pardoned in this connection. He says:

> Circumcision promotes cleanliness, prevents disease, and by reducing oversensitiveness of the parts tends to relieve sexual irritability, thus correcting any tendency which may exist to improper manipulations of the genital organs and the consequent acquirement of evil sexual habits, such as masturbation.

Furthermore, it is generally accepted that irritation derived from a tight prepuce may be followed by nervous phenomena, among these being convulsions and outbreaks resembling epilepsy. It is therefore not at all improbable that in many infants who die in convulsions the real cause of death is a long or tight prepuce. In a case reported by A. H. Baker[12] of Elmira, N. Y., repeated attacks of epileptiform convulsions occurred in a boy aged 5. It was found that there was an adherent prepuce with marked adhesions. After the child was circumcised the convulsions ceased and have not since recurred.

A similar case is reported by Gowers,[13] the famous neurologist, as follows:

> A boy aged 13 had suffered from fits for fifteen months, which commenced with a sudden start of considerable violence, and immediately his legs became strongly flexed, and his trunk bent forward with the head between the knees. He had twelve or fourteen fits a day on various treatments. It was then found that he practiced masturbation; a blister on the prepuce reduced the fits from two to seven daily. He was then circumcised, and the attacks ceased at once, and did not recur.

Gowers also adds,[13] in discussing the treatment of epilepsy:

> Circumcision, if effectually performed, is usually successful, and should be adopted in all cases in which there is reason to associate the disease with masturbation.

We have the further testimony of Moll,[15] who confirms the general opinion that phimosis induces to masturbation. To quote:

> We have further to take steps to allay as far as possible all kinds of local irritation of the genital organs. Among these may be mentioned phimosis and skin eruptions of the genital region, which latter may lead to scratching, and so give rise to masturbation, even apart *from* the fact that the itching itself may favor the occurrence of voluptuous sensations.

With these authoritative observations in mind, we may safely conclude that circumcision is to be regarded as a powerful prophylactic against masturbation and other reflex neuroses that result from preputial irritation.

V. AS A PROPHYLACTIC AGAINST LOCAL COMPLICATIONS IN VENEREAL DISEASE

Surely it is not necessary to offer more than the mere statement of fact, to convince an unprejudiced mind *that circumcision* prevents local complications in the presence of venereal disease. The experience of any one who has treated venereal diseases in a large clinic which is patronized by uncircumcised men of the lower and poorer class is sufficient for the purpose. Balanitis, with its accumulation of natural and pathologic secretions within the cavity of the prepuce, is a complication of such common occurrence as to be expected in every uncircumcised patient. Worse than that, when the prepuce is somewhat longer and tighter than usual, chancres and chancroids may and often do remain long undiscovered, hidden in a mass of unspeakably foul and necrotic matter. Inflammation of the adjoining glands is the natural sequence of the retention and absorption of these unclean secretions. In this connection it is well to remember that there must be cases innumerable. in which syphilitic and chancroidal infection has been spread unwittingly in coitus, as the result of these venereal ulcers, hidden in the preputial cavity. Not infrequently, too, the retention and inflammation become so acute as to produce extensive ulceration and necrosis of the glans and the foreskin itself. Altogether, the picture is a striking and compelling argument in favor of the circumcision of all males, irrespective of whether the foreskin might in adult life be long or short, tight or loose.

VI. AS A PROPHYLACTIC AGAINST BALANITIS

It naturally follows, as Dr. Corbus has mentioned in his statement, quoted before, that in the absence of a foreskin, this form of preputial inflammation is impossible. This condition was first described by Bataille and Berdal,[16] and later confirmed by Scherber and Müller.[17] The etiologic factors are a tight foreskin, which excludes the air, joined with a symbiosis of an anaerobic vibrio and a spirochete. Corbus and Harris,[18] in an extensive study of this disease, remark that this condition may cause deep and wide-spread gangrene, and that "as a prophylactic measure the practice of circumcision should be encouraged; it is absolutely impossible for balanitis to exist in an individual who has been circumcised." To those who condemn circumcision, a brief experience in a clinic located in a neighborhood in which the uncircumcised live and come for treatment must be suffi-

ciently convincing, if their olfactory nerves are normal, that the fourth venereal disease is in itself the best possible argument for universal circumcision.

VII. AS A PROPHYLACTIC AGAINST PHIMOSIS AND PARAPHIMOSIS

What has already been said in favor of circumcision must apply with equal force in reference to the occurrence of phimosis and paraphimosis. Here we have a purely mechanical condition to deal with—one which cannot exist in those who have been properly circumcised. Joly,‡ the French surgeon, estimates that fully 12 per cent. of all infants present a congenital phimosis at birth. It is conceded even by those who condemn ritual circumcision that in the presence of either of these conditions, circumcision is imperatively indicated: conversely, it is apparent that the only way to prevent their occurrence, with all the ills that go with them, is to circumcise all male children.

In elderly men, with the passing of the sexual function, the prepuce undergoes involution with the rest of the genital organs, and as a result, retraction becomes more and more difficult. Chronic phimosis is the outcome, bringing with it a retention of secretions, masturbation for the relief of the irritation, and occasionally the deposit of urinary salts in the preputial cavity and the formation of preputial calculi. In this connection, Corner[7] says:

> Sometimes the timely operation of circumcision does much to save a patient and his friends from remorse, misery and perhaps, shame. Much might be done for the comfort of the individual, and the happiness of mankind in general, if circumcision of the elderly were more frequently undertaken.

Zuckerkandl of Vienna reported thirty cases of preputial calculus, and Velpeau found a stone in the preputial cavity which weighed 130 gm.[5]

It is also interesting to note that the condition of bilharziosis is strongly associated in the literature with the presence of a prepuce. It is the opinion of some writers who have observed this disease that the bilharzia is not taken into the stomach, but that it enters the body through the urethra while the patient is bathing. This is the opinion of J. F. Allen,[19] who has practiced for years in Natal, Africa, and who, in a lengthy discussion of this disease, advises circumcision as the best method of preventing the infection.

Another point of interest worth remembering in connection with the subject of phimosis is that this condition often leads to the maldevelopment, or rather to the lack of proper development, of the sexual parts. It is not unusual to find, in a man otherwise large and well-built, a distinctly infantile development of the external organs. In such cases a tight or long foreskin will almost always be found, and if in these cases circumcision is done, the organ will often take on a startlingly sudden growth. In my own experience I have encountered at least a dozen instances in which this lack of development has been corrected by the performance of circumcision. Lydston,[6] in commenting on this feature of phimosis, says:

> Early circumcision insures proper development of the parts. It is a matter of common observation among physicians that the Jew is, on the average, less frequently sexually maldeveloped than the Gentile. The admirable custom of circumcision may have had much to do with the extraordinary virility and endurance of the Jews.

CONCLUSIONS

In closing this review of the subject, I venture the opinion that there is much to be said in favor of circumcision and very little, or practically nothing, against it. The most that can be said against the operation as a routine measure is that it is sometimes done improperly, with the result that infections of a serious nature follow. This, however, is a matter that should be considered solely in connection with the performance of the operation, and not with the operation itself. If there are men performing circumcision who are tuberculous or syphilitic, and who, because of their ignorance, spread infection to the infants on whom they operate, they should be taken in hand and weeded out by such means as may seem most practicable and feasible. But to condemn circumcision itself because of that fact seems to me to be worse than childish.

Circumcision must be considered one of the most beneficent measures ever devised for sanitary purposes *in human beings, and it is to be wondered at that there* should exist, at this late day, physicians who stand ready to condemn the practice.

It is indeed a curious fact that many, if not most, of those who oppose ritual circumcision are themselves Jews, and I can recall a conversation with an eminent physician, the son of a famous American rabbi, who boasted that he would not permit his sons to be circumcised. It seems passing strange that men should go so far in their worship of the unattainable as to forget that "all that glitters is not gold," even though it be such a worthy appendage as a prepuce. They also seem to forget that the Tenth Commandment specifically forbids us to covet that which our neighbor possesses, and in this general prohibition, we may surely include the prepuce, which the famous master Ricord designated as a "useless bit of flesh."[20]

The pediatricians who see the evils of faulty circumcision or infections resulting therefrom should remember that they see only the exceptional cases in which the normal and usual result has not been attained. They should also remember that circumcision attains its greatest usefulness in adult life, and particularly when the individual is brought into contact with venereal infections. To those who are called on to treat the diseases acquired by men in maturity, the picture is entirely different from that seen by the pediatrist. The advantages which circumcision brings are best seen, not in childhood, but when the child becomes a man, when the pediatrist has lost track of him.

Quoting Lydston again:

> It is strange that with the experience and example of this great race (Jewish) before him, the Gentile has not generally adopted as a hygienic custom the operation of circumcision. *It is the opinion of many eminent physicians that parents who do not have an early circumcision performed on their boys are almost criminally negligent. In this opinion I fully concur.*[21]

With this emphatic statement of belief and many others from non-Jewish sources and confirmed by the preponderance of expert opinion, I do not hesitate to conclude, notwithstanding the teachings of Maas and his supporters, that it is the moral duty of every physician to encourage circumcision in the young—and it is immaterial whether it is done as a religious rite or as a purely sanitary measure.

HYSTERIC BLINDNESS OF BOTH EYES IN ELDERLY MEN

L. NEWMARK, M.D.
SAN FRANCISCO

It is commonly asserted that hysteria is chiefly observed in young persons and in females. As for the element of sex, the impression left on me by my own experience is that the preponderance of females among the sufferers from hysteria in general is not sufficient to flatter greatly the males. Anesthesia, paralysis, contracture, aphonia, double personality, etc., have been observed by me often enough as manifestations of hysteria in men to cause me to doubt a much greater susceptibility to the disease in women. The two cases of hysteric blindness, presently to be recorded, helped to confirm the doubt. I have had only one case of (unilateral) hysteric blindness in a woman to oppose to these. This numerical relation is not in accord with the aggregate experience deduced in 1902 from the literature of the subject by Kron.[1] He found that among 23 cases of unilateral hysteric blindness there were 7 males to 16 females, and in 26 cases of bilateral blindness the proportion was only 4 males to 22 females. Kron, however, overlooked the two cases reported by Barkan[2] of San Francisco, in 1894; had he included them, there would have been 6 instead of 4 males to 22 females. If these figures are to be trusted to illustrate the relative liability of men and women to hysteric blindness of both eyes, they may also be used to show that one-third of the men so afflicted are to be found in San Francisco — a preposterous conclusion of the kind easily drawn from small numbers.

In respect to age, the two cases herein to be dealt with seem to be even more anomalous, for one of the patients had reached an age equal to that of the oldest patient with hysteric blindness — unilateral in that case — of whom I have found mention, and the age of the other exceeded his by six years. Their ages, being uncommon in the circumstances, make their cases interesting; and, coinciding as they do with that period of life in which the effect of time on the blood-vessels of the nervous organs may be revealed by grave and not altogether dissimilar impairment of functions, they make the cases important.

Case 1.—Captain D, an Irishman, aged 60, was led into my consulting-room, apparently blind, Dec. 16, 1905. Until shortly before he had been master of a coasting steamer. He related that he had first noticed about two or three months before this visit that his vision was failing. He could see certain red and green lights at first 6 miles off, then only 5, then 4, then 3. It was the green lights especially that had given him trouble. He had suffered no emotional strain at all until he thought that his sight was failing. Then he worried a great deal, became almost sleepless, and had severe headaches. It was only when he was looking at the lights, however, that he had been conscious of any defect in his vision until, on awakening one morning, two weeks before he was brought to me, he found that he was "totally blind." He had not had lues. Alcohol had been taken moderately. His mother had been a chronic lunatic.

The patient was a man of robust body. Whether led, or feeling his way by himself, his behavior was that of a blind person. Yet he admitted that he was not in total darkness; rather there was a dense fog around him. He could look straight into the bright sun without inconvenience. When the rays of a strong light were focused on the pupils with a lens or mirror, he had a perception of light. Flashes of light were also perceived when a galvanic current was closed or interrupted while the anode was applied to the back of the neck and the cathode to one or the other temple. The pupils reacted promptly to light; their consensual reaction was also distinct. The backgrounds of the eyes were normal. The corneal reflex of the right eye was equal to that of the left, but there was a hypesthesia extending over the right half of the head and trunk and the right extremities. A tuning-fork on the vertex or on the forehead was heard only in the left ear. The tests of smell and taste gave varying results. The deep reflexes and the plantar reflexes were perfectly normal on both sides. The abdominal reflex, which was faint on the left, was absent on the right.

This hemihypesthesia, of which the patient had been unaware until the examination revealed it, was regarded as hysteric, and the lack of sight was considered to bear the same character; wherefore positive assurance was given that vision would be regained and varied suggestion was used to compass that end. In a few days he declared that the mist had become less dense, but he saw things still only as shadows; the five fingers of the observer's hand, for instance, being held up before him appeared as five objects the nature of which he could not discern. Later, red and green could be distinguished as darker and lighter "shadows," the red being the darker "black," and a pronounced green was distinguished as a deeper shade of the same color as a pale green tint which had been submitted to him; but on Jan. 4, 1906, the day on which I last saw him "blind," he still walked like an ordinary sightless person, and, having once come without a guide, he related, on his arrival, that he had fallen into an opening in the sidewalk.

His visits ceased abruptly. After an interval a message was brought that he was an inmate of the U. S. Marine Hospital and could not come because he had no one to lead him. It was therefore probable that not much progress had been made toward a useful degree of vision, if indeed he had not lost what little he had regained.

The next intelligence concerning him was derived from a morning newspaper of Feb. 19, 1906, which, straining its vocabulary of the weird and wondrous, related that a man who had been detained for a week at the Receiving Hospital in the city of Oakland, a mystery to himself as well as to the physicians there, because he had no knowledge of his personal identity, being ignorant even of his own name, had, the day before, suddenly regained this knowledge and now stood revealed as Captain D., but Captain D. no longer blind. In the afternoon this was verified by the patient himself who came in, loudly proclaiming that he could "see perfectly." He was as elated and grateful as one might be who had recovered his vision after a blindness of organic origin, and in his enthusiasm spontaneously offered to submit to any tests we might desire for the study of his case. And on the following day he did permit Dr. W. E. Hopkins to determine, preliminarily, that without correction his vision was from 20/60 to 20/70, with plus 0.5 it was 20/30 in the right eye and with plus 1 it was 20/30 in the left, and that the visual fields were contracted about 10 degrees for blue and green and 20 for red. Then he disappeared again from my view—this time forever. It was soon afterward explained by a friend of his that the exacting duties of some employment which the captain had obtained left him no leisure to fulfil his promise. Later we learned from the same source that he had relapsed twice into blindness, which recurrences finally depressed him so much that on March 1, 1909, he committed suicide.

The calling of a mariner and the age of 60 years are circumstances that do not comport with the current notions of hysteria. In combination with the patient's severe headaches they may have diverted suspicion of the true nature of the man's blindness from the mind of one oculist, who had previously found a tubular field of vision and had based on it an unfavorable prognosis, and may have deluded another into assuming a "*tumor* behind the optic chiasm." The hardy temperament which we are wont to ascribe to those who follow the sea must have been vitiated in this instance by a hereditary influence derived from the mother, who became incurably insane. Toward dissociating the conception of susceptibility to hysteria from the imputation of effeminacy or pusillanimity it may be well to mention that one of Barkan's patients, a mining engineer, had proved his courage in the pursuit of lions and in combat with savages in the wilds of Africa.

---

[1] Kron: Hysterische Blindheit, Neurol. Centralbl., 1902, p. 584.

[2] Barkan, A.: Festschrift des Vereins deutscher Aerzte zu San Francisco, 1894, p. 10.

The headaches from which the patient suffered before losing his sight were calculated to excite an apprehension of serious cerebral mischief of an organic nature, but writers[3] on the subject have pointed out that blindness has occurred especially in those cases of hysteria in which headaches and encephalic symptoms predominated.

Case 2.—An English clergyman, aged 54, having been until then in good health, was stricken suddenly, while in his pulpit, on Sunday, Oct. 24, 1909. "He became completely blind at once," his physician wrote, "but did not fall or lose consciousness." (At the consultation subsequently it was stated more precisely that he became blind, regained his sight, and then lost it again.) "He was able to continue the service," the history proceeds, "and was then led out. Left arm and leg numb and weak, but not helpless. At the end of twenty-four hours hemiplegia more nearly complete, but he has always been able to move the limbs of left side a little. Occasional clonic convulsions in left leg the first day. Can feel touch, but not pain. Tongue in median line, speech and swallowing intact. . . . Pupils dilated equally, and stationary. Sight absent. Extra-ocular muscles and brow and face muscles not affected. No pain except in eyes when exposed to light."

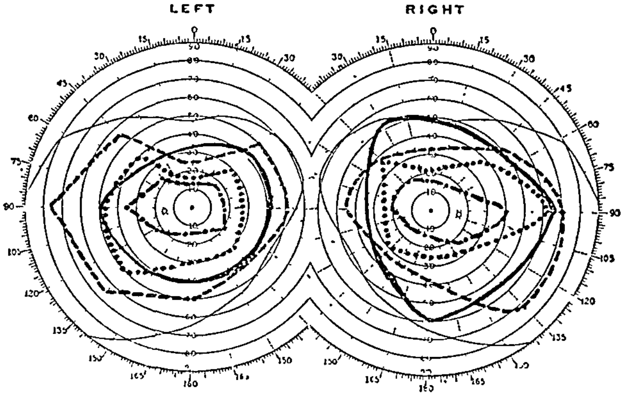
Ten days later it was reported: "Patient has been confined to a dark room on account of photophobia." The pupils were now stated to react to light; the patient could perceive a difference when light entered the room and light no longer gave him pain. There had also been an improvement in the motor power of the left extremities, but the patient was very easily fatigued; the effort of talking or eating exhausted him. Nothing had been found in the urine or in the heart which could have caused the visual or cerebral disorder.

On November 6, that is, thirteen days after the onset of the trouble, I examined the patient at his home, several hours' journey from San Francisco, in consultation with the attending physician. He had been progressing steadily until, as the doctor informed me, "he distinguished light and shade, although he could not see outlines." He could now see enough to perceive that I wore spectacles. Vision with the right eye was less reduced than with the left, the higher degree of amblyopia on the left being probably connected with the anesthesia which was found throughout the whole of that side, on which hearing and smell were also duller than on the right. The patient kept the lids screwed up, as with a blepharospasm from photophobia, but we made an ophthalmoscopic examination of him without much difficulty and found no changes in the fundi. The reactions of the pupils were unimpaired. The movements of the face and tongue were normal, but power in the left upper and lower extremities was diminished; the lower limb was more affected than the upper. The patient could walk, but dragged the left foot and did not circumduct it in the manner commonly observed in organic hemiplegia. There was a perfectly normal plantar reflex on the left, although, probably as a result of the hemianesthesia, it was not quite so lively as the right one; the abdominal reflexes, the knee-jerks and the reflexes in the upper extremities were equal on the two sides. There was no astereognosis.

The patient was very hopeful in regard to the recovery of his sight and of the power of motion, and the assurances given him in order to fortify his confidence seemed to be rather superfluous.

By November 20 the doctor reported that "the patient sees very well now, but cannot read yet. Print is blurred to his eyes. He walks about with a cane with considerable favor to the weak leg." On Feb. 4, 1910, the account of him read: "He walks perfectly well and strong on both legs. He cast his cane aside several weeks ago. He is apparently in normal condition now with the exception of one eye. It gets tired quickly and does not see as clearly as the other." Later reports announced that "he is real active on his legs and his sight is good," but his memory was poor, mental effort confused and exhausted him, so that, being unable to produce new sermons or to attend to other clerical duties without suffering distress, he had to be retired.

As soon as I was informed that the patient was able to leave his home I began my endeavors to induce him to come to San Francisco, in order to examine him more thoroughly than circumstances had previously permitted; not succeeding in this, I pursued him with my importunities across the continent, and at last, about three years and a half after that seizure in the pulpit, through the kindness of Dr. B. F. Hodsdon of Miami, Fla., I obtained two sets of charts of his visual fields, one of which is here reproduced. Dr. Hodsdon took the fields on three different days and found that they varied.[4] The perimeter chart which is here supplied is the result of the examination of March 26, 1913. It will be observed that the field for white of both eyes is contracted, more of the left than of the right. The salient abnormality is, however, the extension of the field for blue beyond that for white, especially in the left eye, in which the field for red also in some meridians extends beyond that for white. The field for blue may perhaps be regarded as a little larger than normal. Red and green give irregularly contracted fields. There is no reversal of the color fields.



Case 2.—Fields for white and colors taken March 26, 1913. Dark continuous line indicates field for white; dash line outlines blue, dotted line red, line of dots and dashes green.

The perimeter charts dated April 25, 1913, also show the periphery of the fields for blue extending beyond the outlines of the white fields. This time the peculiarity is observed in the right eye as well as in the left: in both the temporal part of the blue extends from 25 to 30 degrees beyond the white fields.

A long letter written about this time by the patient contains no evidence of intellectual feebleness except his own statement that intense thinking causes "everything to become dense and cloudy." When he hurries or exerts himself he becomes conscious of a weakness in the left lower extremity; but whatever impression of any degree of disability might be derived from this description of his condition is pretty well effaced by his concluding denomination of himself as "a very well-satisfied individual."

---

[3] Kron: See Footnote 1. Dieulafoy: La cécité hystérique, Sem. méd., 1905, No. 50, p. 591, lays special stress on headache as a forerunner of hysteric blindness.

[4] No information was furnished as to the size of the test object used in the perimetric examinations, nor have I any data as to the patient's present visual acuity.

In the first case, after a period of gradual diminution of vision, or, at least, of increasing apprehension of loss of vision, sight was suddenly lost, and, after an interval, as suddenly regained under circumstances which must dispel all doubts as to the nature of the blindness. In the second case, contrariwise, there was no premonition: like the disasters which may result from organic cerebral disease and are not uncommon at his time of life, paralysis and blindness befell this patient in the midst of his professional activity, and again, like the effects of organic disease, and unlike the dramatic issue in the first case, they receded only by degrees.

An emotional etiology could not be clearly elicited. In a very small town the minister "ran his godly race." He had a large family and a very meager stipend, but it could not be ascertained that his placidity was disturbed by anything more than the cares of his parishioners, and no unusual excitement had preceded the calamity which overtook him in his pulpit. The profession that he is "a very well-satisfied individual," quoted above, may be taken into account in determining his kind of temperament. His physician believed that the imputation of his being subject to such a disorder as hysteria would be extremely offensive to him.

The hemihypesthesia in the clergyman was of the same character as that of the mariner, and did not differ considerably from it in intensity. It will probably not be asserted that this "sensory" or "mixed" hypesthesia (so called because the special senses were more or less involved), which is so common in hysteria, was caused by an organic lesion in the first case; nor is there any necessity for assuming any such lesion in the second, despite the association of the affection of sensibility with a disturbance of motor power. This motor disturbance had no indisputable characteristic of organic origin, such as a Babinski sign; still, with the aid of some authors,[5] the hemiparesis, with greater involvement of the leg than of the arm, and the mixed hemihypesthesia might be referred to a lesion affecting the posterior part of the internal capsule; but such a lesion could not be conceived to cause the blindness. A unilateral affection would have caused a hemianopsia (or, according to the teachings of a former time, a crossed amblyopia with concentric limitation of the visual field) associated with the hemianesthesia; to make the patient "completely blind at once," a simultaneous injury to optic fibers or centers would have been required in the other hemisphere. The blindness resulting from bilateral lesions would consist in the addition of a right and a left homonymous hemianopsia; like the blindness of the two patients now under discussion it would be compatible with normal pupillary reactions, clear media and normal disks, and after having been complete for a longer or shorter period, it might be followed by a return of vision limited, however, to a field closely contracted around the fixing-point. I can say from my own experience in a case of bilateral softening of the occipital lobes in a woman of 65, and in two cases of blindness following a fall on the back of the head in young persons, by which no doubt the occipital lobes suffered injury, that from such lesions there may result a state of blindness which may be distinguished from hysteric amaurosis only by considering all the clinical features.

There are, however, in my second case positive traits in the picture which determine its interpretation as hysteric. These are, first, the photophobia and the appearance of blepharospasm. Dieulafoy writes, "A considerable number of patients affected with hysteric blindness keep their eyes obstinately closed like persons suffering from keratoconjunctivitis, who close their lids because they fear the light." He cites a case of Saint-Ange's, in which the patient had a spasm of the orbicularis, which was ascribed to a certain degree of photophobia, although the blindness was absolute. Then there are the visual fields which, although not charted until three years and a half after the attack of paralysis and blindness, still exhibit an extension of the field for blue far beyond that for white—a hyperchromatopsia which, experienced oculists inform me, is hysteric, an opinion for which there is support in a chapter contributed by De Schweinitz to Posey and Spiller's work on "The Eye and Nervous System."

Still, *falsum in uno* need not imply *falsum in omnibus;* for some disturbance may have occurred in the cerebral circulation which caused the left hemiparesis and at the same time provoked the mental state of which the blindness was a manifestation. The weight of the evidence, however, inclines to the conclusion that the whole constitutes a remarkable example of the power of hysteria to mimic cerebral disease.

EXTRATHORACIC AND INTRATHORACIC ESOPHAGOPLASTY IN CONNECTION WITH RESECTION OF THE THORACIC PORTION OF THE ESOPHAGUS FOR CARCINOMA [*]

WILLY MEYER, M.D.
Attending Surgeon to the German and Post-Graduate Hospitals
NEW YORK

A year ago surgeons were still trying to demonstrate the possibility of successful resection of the esophagus for carcinoma. Gastrostomy for feeding and excision of the tumor with the working out of a safe method of inverting and closing the oral esophageal stump, which was left *in situ* within the thorax, appeared to be all they expected to achieve. The construction of a new tube for the act of swallowing—esophagoplasty—was a question that was given less consideration.

Since then the surgery of the esophagus has made such rapid strides forward that to-day the operator is obliged to include the question of the best way of forming a new esophagus when planning his operative work for the removal of a malignant esophageal stricture.

How did this rapid change come about? It seems that two factors are responsible for it:

1. The experimental designing of a new method of gastrostomy, the Jianu operation,[1] which incidentally represents the first step of inferior (or lower) esophagoplasty, and its introduction into human surgery.[2] By this operation a new tube is made by the dissecting off of a portion of the major curvature of the stomach, its

transposition under the skin of the thorax—extrathoracically—from below upward.

2. The performance of two resections of the esophagus for carcinoma in man, in each of which the oral stump of the esophagus is successfully transposed under the skin of the thorax from above downward, superior (or upper) esophagoplasty.[3]

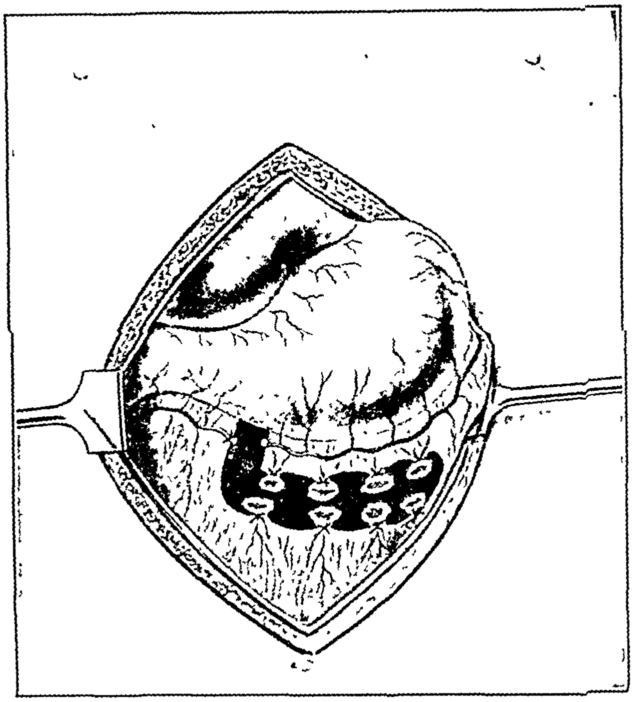

Fig. 3.—Jianu's gastrostomy and inferior esophagoplasty. Median incision; double ligation and division of omentum majus up to the point at which left inferior epiploic artery turns onto the stomach. Double ligation and division of right inferior epiploic artery; exposure of major curvature of stomach.

In order to avoid repetition, it seems best first to review briefly the operations devised for esophagoplasty prior to the year 1912.

BRIEF REVIEW OF OPERATIONS FORMERLY DEVISED

1. Esophagoplasty[4] by Means of Skin-Plasty (Bircher).[5]

Bircher showed as early as 1894 that a well-functionating, new tube for swallowing can be made from the neck down to the stomach by plastic work on the skin of the anterior aspect of the thorax.

2. Inferior Esophagoplasty with the Help of a Totally Excluded Coil of Jejunum (Wullstein,[7] Roux[8]).

The operation is done in three (or four) stages. A coil of the upper jejunum is totally excluded, remaining, of course, attached to its mesentery, transposed under the skin of the thorax and then with its lower aperture connected with the stomach (Fig. 1). Herzen, Lexer and Frangenheim have proved the feasibility of the method in cases of intractable cicatricial stricture of the esophagus. Their patients recovered. Gangrene of the transposed coil easily spoils the result.

3. Inferior Esophagoplasty with the Help of the Totally Excluded Transverse Colon (Kelling,[9] Vulliet[10]).

The transverse colon, totally excluded, also represents useful material for the formation of a new extrathoracic subcutaneously placed esophagus (Fig. 2). As stated before, however, this kind of plastic work, ingenious as it is and important as it may prove to be, after all, for the surgery of the esophagus in the future, requires a series of operations, the first of which always has to be a gastrostomy according to one of the older well-known methods.

Jianu's gastrostomy promises to simplify this chapter of operative surgery, inasmuch as it provides for the formation of the lower portion of a new esophagus—inferior esophagoplasty—at the same time.

OPERATIONS RECENTLY DEVISED

4. Inferior Esophagoplasty with the Help of a Dissected Portion of the Major Curvature of the Stomach (Jianu).

Technic of Jianu's Operation.—Jianu makes use of the major curvature of the stomach for the creation of a rather long tube, one end of which remains in connection with the gastric fundus, while the other free end can be drawn up. Before Jianu, others had tried to solve the task in a similar manner. Depage[11] by making use of the lesser curvature, and Hirsch[12] of the anterior wall of the stomach. Jianu's procedure means a decided step forward in comparison with the other two. Briefly described, it is as follows: median abdominal incision above the umbilicus; pulling forward of stomach; double ligation and division of major omentum from a place about 2 inches from the pylorus up to the region in which the left inferior epiploic artery turns onto the stomach. Liga-

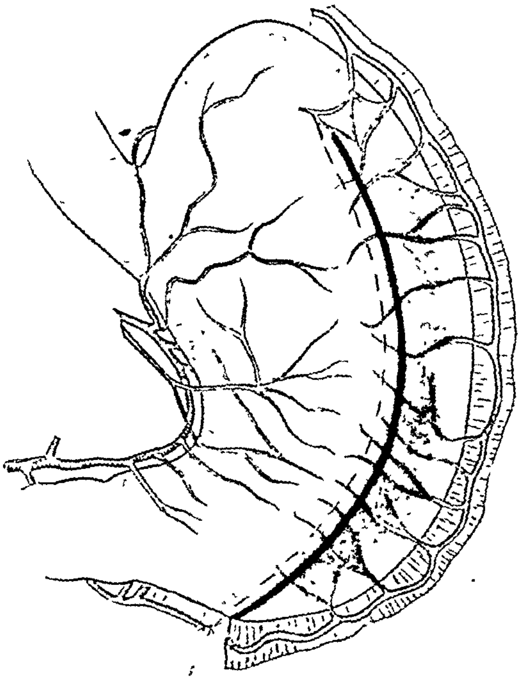

Fig 4.—A mattress suture (dotted line) divides the lower one-third of the stomach with its major curvature from upper two-thirds; scissors then cut the stomach along the heavy line.

MEDICAL CO

ture of right inferior epiploic artery next to the first omental stump, formed by the ligation, completely baring the stomach wall (Fig. 3). A mattress suture is run from here through the entire thickness of the stomach about 1½ inches distant from and parallel with the greater curvature (Fig. 4, dotted line), the stomach having been lifted up by the assistant in order to have the contents run toward the lesser curvature. By placing a clamp (better still, two equally curved clamps), corresponding to the line of the major curvature, the asepsis of this part of the operation can be materially improved and the work simplified[13] (Fig. 5). Division of the stomach with scissors right below the suture line (Fig. 4, heavy line); major curvature turned up and temporarily wrapped in a piece of sterile gauze; Connell's suture from end of mattress suture to end of stomach flap forms the latter into a tube: "Jianu's tube" (Figs. 6 and 7). A second continuous suture inverts the first along its entire length; temporary inversion of end of tube by two or three sutures, their ends being left long (Fig. 8). Stomach turned so that base of Jianu tube corresponds to upper angle of abdominal wound, where it is secured by a few stitches. Closure of lower half of abdominal wound. Jianu's tube placed on chest to the left of sternum, to measure its length; horizontal incision at level of upper end of tube, skin of thorax thoroughly undermined and new tube pulled up with long curved forceps which catches the end of the inverting sutures (Fig. 9). The latter removed, and mucosa—*not* the entire thickness of tube—lined to skin of transverse incision; a strip of gauze in either corner of wound for brief drainage (Fig. 10); temporary packing of the orifice of the tube with gauze; closure of upper half of abdominal incision; dressing.

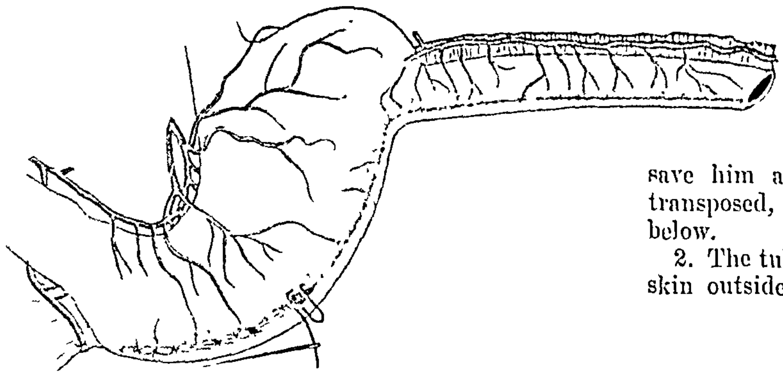

Fig. 6.—The major curvature flap formed into a tube—Jianu tube—by means of a continuous Connell suture; a second running suture (preferably Cushing's) secures the first row.

A new tube of ample size, from 18 to 25 cm. long, with good blood-supply and surrounded completely by peritoneum, has thus been formed, affording splendid material for the making of a new canal through which the patient will be enabled to pass his food down to the stomach. Its base remains in connection with the gastric fundus. The placing of its free end decides the location of the new esophagus and additional operative procedures. If transposed *outside* under the skin of the thorax, the first stage of *extrathoracic* esophagoplasty has been accomplished. If pulled up into the pleural cavity, through a hole of the diaphragm as proposed by me[14] it can be used to replace the lower portion of the esophagus that had been resected for carcinoma: *intrathoracic* esophagoplasty.

So far I have carried out Jianu's operation in three patients. In the first case needle and thread were used throughout. In Cases 2 and 3 I tried Hültl's wire-stitching instrument. All three patients made a good recovery (Figs. 11-13). The new tube was in each case placed extrathoracically.[15]

OBSERVATIONS AND REMARKS

1. In view of the presence of the vasa brevia (the branches of the splenic artery) the mattress suture and incision can well be run 1½ or 2 inches further up toward the fundus of the stomach, past the onward turn of the left inferior epiploic artery, a procedure which lengthens the tube considerably. Of course, the longer the tube, the better for the patient; a difference of ½ inch may save him another operation, if the oral stump, also transposed, meets the end of the tube pulled up from below.

2. The tube, when pulled up through the tunnel of the skin outside the thorax, should be put on the stretch. Its ample blood-supply will prevent gangrene. Its upper end can thus usually be brought up to the level of the third and often that of the second rib.

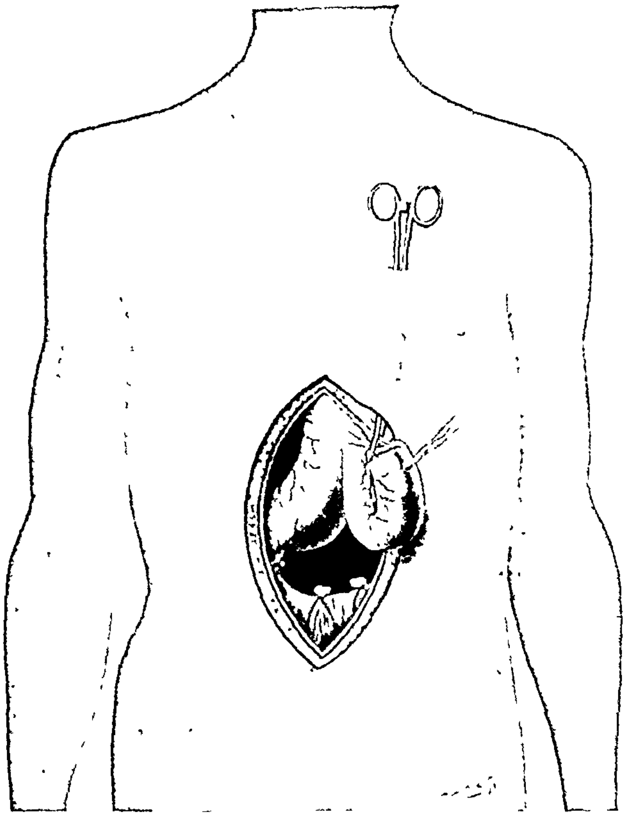

Fig. 9.—Stomach turned so that base of tube at fundus is flush with upper angle of abdominal incision; short transverse incision over third left costal cartilage, or above the same, according to length of tube; long curved dressing forceps there introduced under skin meets left forefinger of surgeon pushed upward from upper angle of abdominal wound; a wide subcutaneous wound is made. Forceps passed under bridge catches the sutures of inverted upper end of tube, which have been left long (in illustration the subcutaneous canal is shown very narrow by mistake; the forceps should catch the ends of all three sutures instead of only two).

---

[13] If the major curvature is pulled into a straight line by an assistant, a straight clamp will probably do just as well.

[14] Meyer, Willy: Centralbl. f. Chir., Feb. 22, 1913, No. 8.

[15] Meyer, Willy: Ann. Surg., September, 1913.

3. There is no sphincteric action at the base of the tube; hence it often leaks in spite of its length, if not blocked with gauze at the upper end (Fig. 12) or compressed by a truss-like apparatus. This may become a source of great annoyance to the patients and forbids this operation in case the surgeon intends the formation of a gastric fistula only. Here the old, well-tested and satisfactory methods of gastrostomy (Witzel, Kader, Ssabanejew-Frank, Senn) should be resorted to. This leakage of gastric contents may also spoil the result of additional plastic work that may become necessary. The next pressing task to be solved therefore is to improve the functional result of Jianu's tube. It is possible that twisting the tube from 60 to 90 degrees or more (according to Gersuny's method for resection of the rectum) may overcome the leakage, perhaps also a slight modification with reference to the opening communicating with the fundus of the stomach (possibly *the smaller* the better), or when suturing the upper half of the abdominal wound, for instance, lifting the stomach up by one or two sutures only, so that a kind of kink occurs at the place where the tube enters the abdomen, or by constricting the stomach at this place in some manner. A correct explanation of this leakage at the opening of Jianu's tube probably is that the normal peristaltic movements of the stomach persist in the dissected portion on account of the presence of a branch of the left pneumogastric nerve within the wall of the new tube. Further observations will have to decide this point.

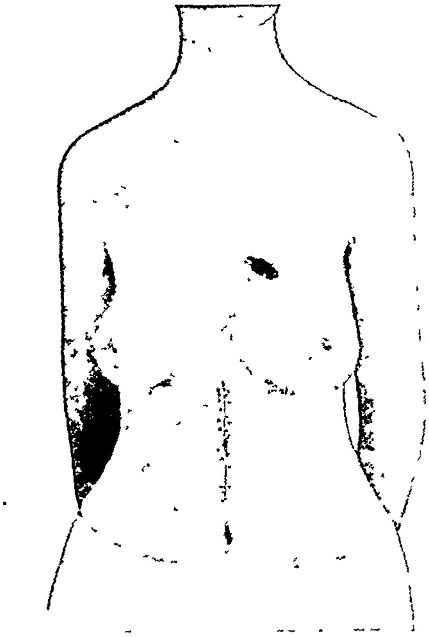

Fig. 13.—Third patient with same operation, also done under *venous anesthesia and with Hültl's instrument* (March 27, 1913). Base of tube at gastric fundus lifted up and secured to parietal peritoneum by six retention sutures; rapid recovery. Opening corresponds also to cartilage of third rib Tube forms a distinct serpentine under skin; it might well have been put more on the stretch and would then have easily reached the second cartilage. During after-treatment an outflow of gastric contents is observed off and on, which suggests normal peristaltic motion in the tube in the direction from cardia to pylorus, very likely due to the branch of the left pneumogastric nerve which runs within the wall of the tube. Plugging the upper opening with gauze and compressing the tube against the ribs by means of a truss-like apparatus with water-pad controls the outflow satisfactorily.

4. Reduction of the size of the stomach to two-thirds of its width does not interfere any more with the gastric function, than does resection of the stomach in the *transverse direction; the patients thoroughly enjoy their* meals.

5. Subcutaneous transposition of the new tube is preferable to submuscular.

6. The patients chew their food, thus enjoying its taste; by using the physiologic action of the saliva they stimulate gastric secretion; then they deposit it in some kind of warm fluid, broth, milk or water and wash the food down into the stomach through a funnel and tube. *The latter is introduced only at times of meals; it is not* permanently worn. Intelligent patients need only turn the head forward and downward and blow the chewed food, with the help of a special, cup-like mouth-piece, through the Jianu tube into the stomach (Trendelenburg).

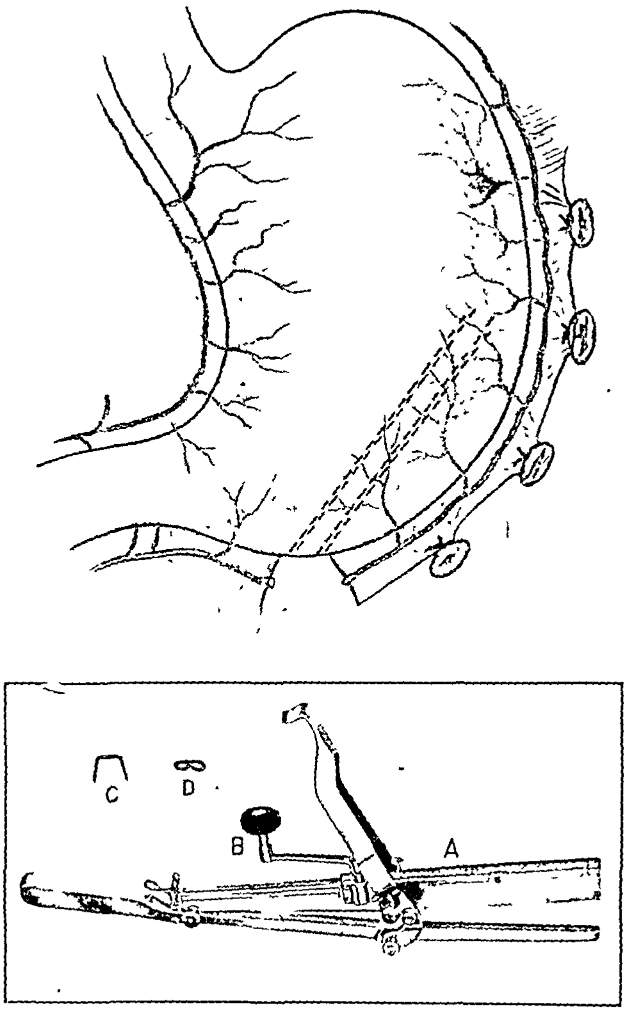

Fig 14.—Lower illustration shows Hültl's wire-stitching instrument. *A* represents broad, square crushing clamp which harbors the four rows of staples (*C*). *B* shows crank; by turning same five *times to the right after the clamp has been closed the staples are* driven entirely through the tissues (wall of stomach or intestines), and either side bent inward (*D*), having met the resistance of the other branch of the clamp beneath. The bent staples are gradually pushed off in the course of healing and discharged through the rectum; they never do any harm The upper illustration shows the double row of through-and-through wire staple sutures placed; the crushed center portion between the two inner rows is not shown

7. On basis of operations on dogs, we have made use of Hültl's wire stitching instruments to great advantage *in the formation* of the Jianu tube in the last two patients operated on. *Hültl's instrument* (Fig. 14 *a*) combines a firm compression of the tissues, to be divided, with rapid, easy and safe placing of a double row of *wire staples between which division is made* (Figs. 14 to 17). The operation on the stomach is therefore

rendered absolutely dry and, of course, more aseptic. The time of operation is also shortened, a point which in addition to the first may be of importance in weak patients.

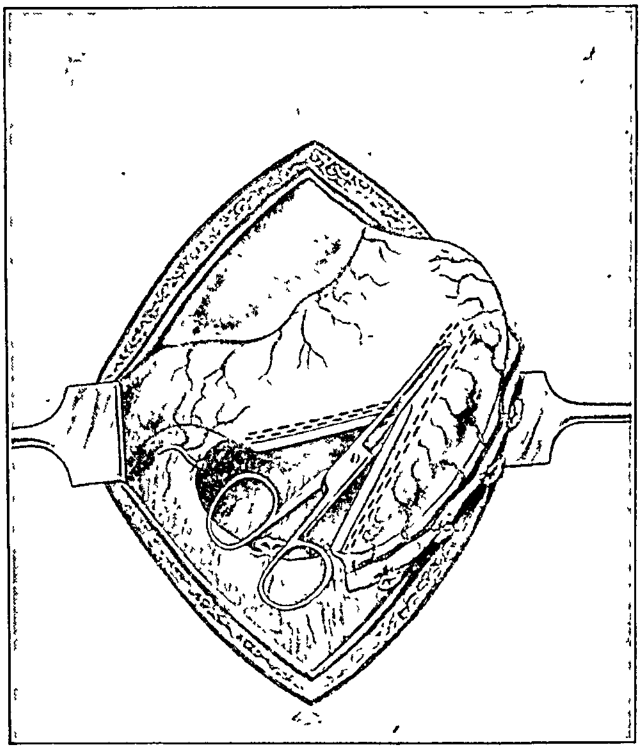

Fig 17—A second double row of staples is placed at an obtuse angle with Hültl's second (smaller) instrument beyond the turn of the left inferior epiploic artery, scissors traverse the dry, crushed center portion between the inner rows

5. *Inferior Esophagoplasty by Means of the Stomach and First Horizontal Portion of the Duodenum (von Fink).*—Not infrequently a cancer of the cardia does not grow upward involving the lowest portion of the esophagus, but advances on to the cardiac portion of the stomach in the shape of a cap. Here the base of Jianu's tube would lie in an area possibly already involved in the malignant disease. In keeping away from the fundus at an adequate distance, the tube would be of no use on account of its shortness. Here one of the old methods of gastrostomy should be done, or, if extrathoracic esophagoplasty were desired, von Fink's operation would be indicated.

6. *Inferior Esophagoplasty by Means of the Stomach and Distal End of the Resected Esophagus.*—Ach[17] proposes to make use of the stomach plus healthy distal stump of the esophagus after resection in its middle. Rehn[18] and Roepke[19] have worked in a similar direction. The procedure, if feasible, will be ideal on account of the presence of the normal cardia. The operation, however, means loosening the latter from its diaphragmatic attachment, and the necessity of providing against hernia through this hole. It also is to be seen how division of both pneumogastric nerves will affect the physiologic action of the cardia. Further, gastrostomy or inferior esophagoplasty must be done as the final step of the operation at the same sitting — a decided disadvantage.

The performance of gastrostomy after Jianu, as well as after von Fink and Ach, has no *raison d'être* in cases of cancer of the esophagus, unless the surgeon also desires to transpose the oral stump of the esophagus after resection, a procedure worked out by von Mikulicz and Kelling[20] years ago. The experience gained from two patients treated with this transposition of the oral stump of the esophagus after resection has shown, as mentioned before, that it can be done successfully and without the appearance of necrosis. This fact, in conjunction with the lower half of extrathoracic esophagoplasty, accomplished with the help of Jianu's gastrostomy (or von Fink's and Ach's procedure), has rapidly pushed on the evolution of this chapter of esophageal surgery. We have learned that extrathoracic transposition of the oral stump is the simpler and safer procedure, and it has therefore to be considered the operation of choice.

Further observations in man will show how long the oral stump may be without risk of partial necrosis. The latter must be avoided at all hazards, as it spoils the prognosis of subsequent plastic work which may become necessary, or even renders it impossible altogether. If it is of sufficient length to meet the opening of Jianu's tube, end-to-end suture, as mentioned, will finish the extrathoracic esophagoplasty in the happiest way (Fig. 21). If too short, a subsequent skin-plasty after Bircher[5] must bridge the defect (Fig. 22). Or, if further operating was not desired, or was contra-indicated, then a rubber tube, connecting both openings (Gluck,[22] Perthes) will establish the continuity of the tube and therewith enable the patient to swallow his food, a consummation most ardently desired by all.

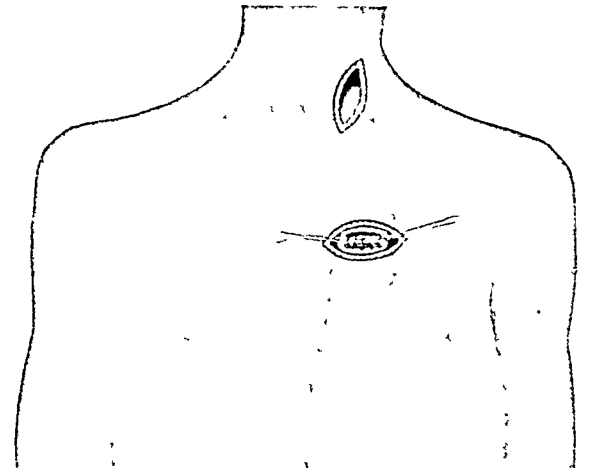

Fig. 21.—Last step of the two-stage operation just described.

It is in view of this invariable desire on the part of these patients in whom gastrostomy was performed that

[17] Ach, Alwin: Berl klin. Wchnschr., 1913, No. 18, p 853
[18] Rehn, E.: Centralbl f. Chir, 1913, No 28, Supplement, p. 50.
[19] Roepke, W.: Berl klin Wchnschr, 1913, No. 18, p. 853
[20] Kelling, G. E.: Centralbl. f. Chir., 1904.
[22] Gluck, Th.: Berl klin Wchnschr., 1898, No. 42.

I have decided not simply to close the thorax in cases in which exploratory thoracotomy has shown the disease inextirpable, but to divide the esophagus in proper distance from the upper pole of the tumor and then transpose the oral stump extrathoracically, after closure of the distal part by inversion and suture (one personal observation so far).

From my experience gained in six cases of esophageal resection for advanced carcinoma I should advise to leave alone an infiltrating carcinoma behind the aortic arch which covers several inches of the tube, when performing thoracotomy on patients who show symptoms of *complete obstruction for some time* prior to operation. Attempts at removal will greatly weaken the resisting power of these reduced patients and eventually force the surgeon to continue radical work much against his wishes. On the other hand, palliative work — division of the esophagus above the stricture, closure of the distal end and extrathoracic transposition of the oral stump, as described before — do not tax the patient to any extent and will brighten the rest of his life.

It is, as a matter of course, impossible at the present moment to say which method of extrathoracic esophagoplasty will prove to be the preferable one. If the task of preventing regurgitation of stomach contents through the Jianu tube can be solved, then this method of gastrostomy and inferior esophagoplasty will be the operation of choice, principally on account of its simplicity and comparative absence of danger. If it will be shown, however, that this cannot be done and that the digestive effect of returning stomach juice will spoil plastic work that may become necessary later on, then the Wullstein-Roux method, or very likely Kelling-Vulliet's transposition of the excluded transverse colon will best be resorted to. At the present juncture it should be emphasized again that efforts of surgeons should be directed toward improving the functional working of Jianu's tube.

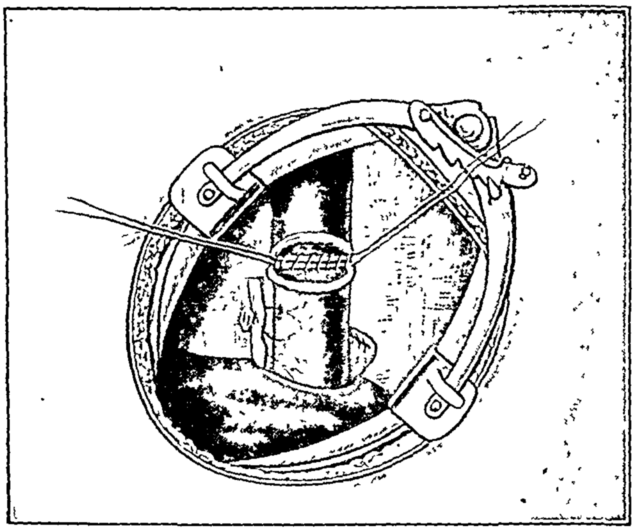

Fig. 24.—Inverted tip of Jianu tube released and cut off; redundant gastric mucosa clipped and both openings in process of end-to-end union by suture. There is splendid blood-supply up to the tip of the Jianu tube from the left inferior epiploic artery within the ligated major omentum, which latter always is to point toward the patient's right.

INTRATHORACIC ESOPHAGOPLASTY, EXPERIMENTAL

In cases in which examination previous to operation has shown the cancer to be located within the lower third of the esophagus, or localized right at the cardia itself (scirrhus) and immediate esophagogastrostomy does not appear feasible on account of the distance of the proximal end, the excellent plastic and well-nourished material of Jianu's tube makes one wonder whether or not the excised lower portion of the esophagus or cardia might be immediately replaced by this tube if brought up intrathoracically into the pleural cavity through the foramen esophageum of the diaphragm or alongside the cardia which had been closed by sutures after the resection (Fig. 23), its free opening to be united by end-to-end anastomosis with the oral stump of the esophagus which otherwise remains *in situ* undisturbed (Fig. 24).

CONCLUSION

As stated before, intrathoracic esophagoplasty, when properly worked out, would seem to be an ideal operation. If further observations in man, however, should prove that the transposed oral stump of the esophagus, no matter how long, has no tendency to become necrosed in its distal portion, but will live, as a rule, further experimental work for the perfection of intrathoracic esophagoplasty will be less urgent and extrathoracic esophagoplasty will become the operation of choice for resection of carcinoma in any part of the esophagus.

700 Madison Avenue.

A CASE OF RHINOPHYMA SUCCESSFULLY TREATED BY "DECORTICATION"

AIMÉ PAUL HEINECK, M.D.
CHICAGO

For the following reasons and others, I report the following case of rhinophyma. The photographs of the patient were taken before and after the surgical intervention.

1. This chronic disease of the nose, although it is not painful and occurs almost invariably in males, who, as a rule, are less sensitive than females to facial disfigurement, always exposes its victims to ridicule, often makes employment difficult to obtain and not infrequently hampers a patient's whole career. Hebra gave the name of "rhinophyma" to this disease.

2. Owing to the fact, that in the treatment of this affection, medicinal and other non-operative measures never give satisfactory results, patients soon acquire the erroneous impression that cure is impossible.

3. Though Ollier long ago demonstrated that pound-nose (called by him *éléphantiasis des buveurs*) can be *successfully treated by decorticating* the nose, that is, by removing the diseased tissues, by the aid of the thermocautery or cutting instruments, surgeons in general seem to ignore the fact that this unsightly deformity can be corrected by an operation of great simplicity and of unfailing efficacy.

4. Complicated operative procedures have been devised for and recommended in the treatment of hammer-nose. Being based either on inadequate knowledge or faulty interpretation of the pathology of this condition all such operative measures should be discarded.

5. Some diversity of opinion exists as to the etiology and pathologic anatomy of rhinophyma. Coplin, who made the histologic examination of the tissues removed from Keen's[1] patient, diagnosed the condition from the pathologic point of view as a soft fibroma of the skin

---

[1] Keen, William H.: Rhinophyma, Ann. Surg., 1904, xxxix, 665.

with distention of the acini and possibly a hyperplasia of sebaceous glands.

All observers are agreed that the diseased part presents an enormous hyperplasia of the connective tissue of the corium, a thickening, dilatation, tortuosity, a numerical increase of the cutaneous arteries, veins and capillaries and an increase and hypertrophy of the sebaceous glands, the excretory ducts of which show marked lengthening and dilatation. The latter is caused partly by the retained secretion, partly by the active hyperplasia of the glands.

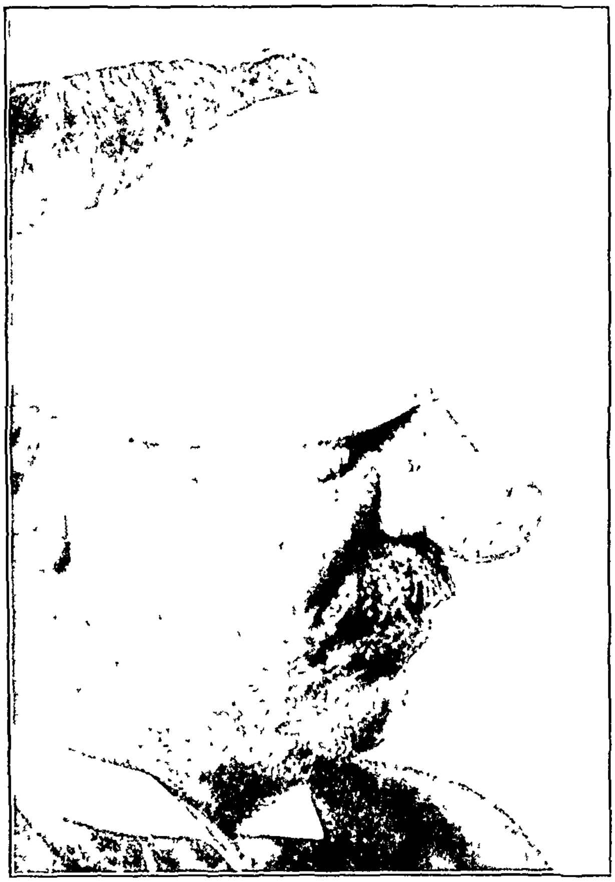

Fig 1.—Case of rhinophyma before operation.

History.—Mr. L., a Bohemian tailor, aged 48, married, was referred to me by Dr. Stulik for a nasal deformity which, according to the patient, made its appearance thirty-one years ago following an attack of chicken-pox. The patient eats lightly, drinks several glasses of beer daily, and does much walking. The family history is negative. The patient's health has always been good, and the physical examination, outside of the face and nose, is negative. The facial appearance frequently subjects him to embarrassment and mortification. Many physicians have treated the condition non-operatively with no improvement.

Examination.—The entire facial skin was seborrheic. The nose and the bordering cheek-areas were dusky red and presented a large number of thickened, dilated and tortuous cutaneous vessels, and many dilated, large, gaping sebaceous gland orifices, some of which were plugged with inspissated secretion. Many pustules, coexistent with acne rosacea, were on the cheek. The external portion of the nose was greatly hypertrophied; its tip consisted of a soft lemon-sized mass. The hypertrophy was limited to the superficial external portion and did not extend beyond the nasal orifice. The patient was sent to the hospital, was etherized, the eyes protected and the operative field (nose and cheeks) painted with tincture of iodin. Although decortication of the nose has been performed successfully under local anesthesia[2] (cocain, its synthetics, freezing mixtures, etc.), I prefer in these cases to use a general anesthetic.

Operation.—The index-finger of the left hand, introduced into one of the nostrils, stretched the soft tissues and held the thickness of the nose under control. This facilitated the modeling of the wings of the nose and guarded against the removal of too much tissue. The exuberant tissue masses on that side were then ablated with a sharp razor; the finger was introduced in the opposite naris and the same procedure repeated on the other side, care being taken during the entire operation not to injure the osteocartilaginous framework of the nose. The intent was to remove almost the entire diseased cutaneous portion of the nose, as the pathology of the disease is in this cutaneous covering. In rhinophyma, the nasal bones, the nasal cartilage, their fibrous covering and the endonasal lining show no apparent change and therefore should not be molested. To make the nose more presentable some paring was done here and there with scalpel and scissors, until the form of a normal nose was reached. It could easily be seen that the tissue *removed contained degenerated and cystic sebaceous glands filled with epithelial débris and sebum.* The operation somewhat resembles the whittling of a block of wood with a jack-knife.

Postoperative History.—The hemorrhage, profuse at first, was readily checked by compression with sterilized gauze. To prevent its recurrence, a hard-rubber nasal tube was introduced in each nostril, counter-pressure being thus secured from within against the pressure exerted from without by the gauze and bandage. The nasal tubes were removed in twenty-four hours. For the first forty-eight hours the postoperative treatment consisted of hot boric compresses applied every two hours to the operative wound. After that time the part was dressed with calamine lotion. Recovery was uneventful. At the end of eight weeks the wound was completely epidermized.

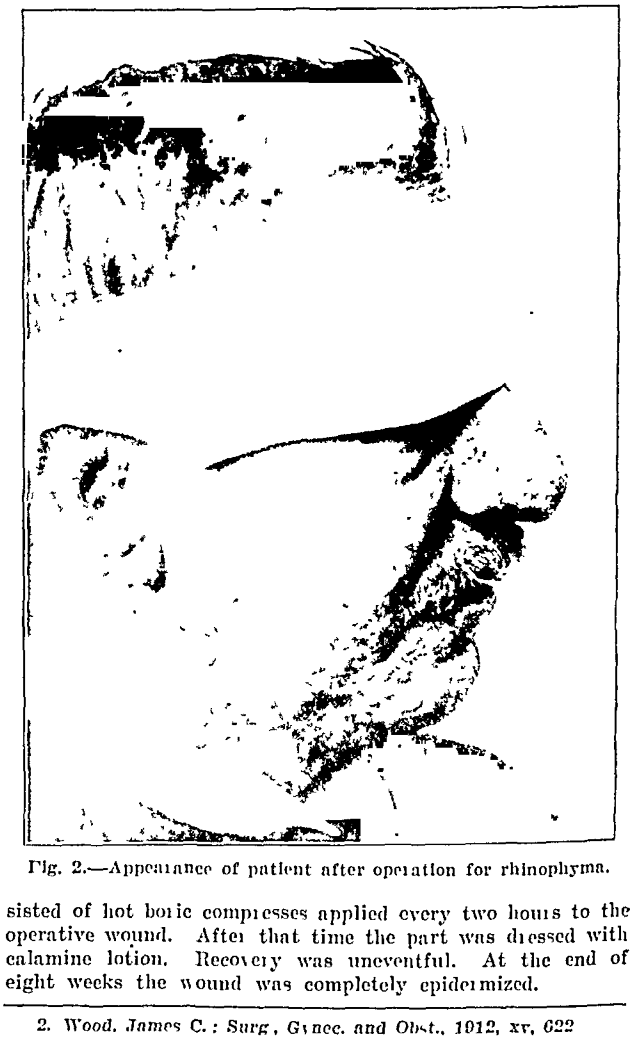

Fig. 2.—Appearance of patient after operation for rhinophyma.

---

2. Wood, James C.: Surg., Gynec. and Obst., 1912, xv, 622

A number of points of interest are presented by this case of rhinophyma:

1. Its occurrence in a man whose occupation does not entail exposure to inclement weather, who is fairly moderate in his consumption of alcoholic beverages and who gives no history of gastric irritation or disturbance. The etiologic influence of alcohol is hard to determine; there are many alcoholics and but few cases of rhinophyma.

2. The fact that all but one of the patient's medical advisers (and he consulted a goodly number) seem to have been unaware of the relief which surgery offers in this condition.

3. The simplicity, safety, efficacy and short duration of the operative intervention, which consists in removing almost entirely the cutaneous covering of the nose, while carefully respecting its osteocartilaginous framework. A covering of greater or less thickness of the soft tissues must always be left. This direct operation is limited to the external superficial more or less modified parts. No complementary, autoplastic or skin-grafting operation is performed.

4. The satisfactory result, which can be seen when the photograph taken immediately before the operation is compared with that taken shortly after the patient's discharge. The new complete skin-covering for the nose was derived from the dermal margins of the wound and from the epithelium of the abundant and deep-lying remains of sebaceous glands.

In cosmetic surgery of the face I discard the thermocautery for the removal of exuberant tissues. It makes the employment of ether anesthesia dangerous. It has always seemed to me that the scar resulting from the cautery is less satisfactory from the esthetic point of view than the scar which results from cutting operations.

HAIR-BALLS OF THE STOMACH AND INTESTINE *

LEDRA HEAZLIT, M.D.
AUBURN, N. Y.

The rarity of hair-ball coincident in the stomach and in the intestine has led me to report the following case, which also has an unusual symptomatology:

History.—The patient, H. C. A., aged 13, the daughter of a physician, with the exception of the usual diseases of childhood and a pneumonia at the age of 11, had always been in good health. When about 2 years of age she developed the habit of sucking her right thumb and at the same time twisting and pulling her hair with the left hand. At the age of 5, she was first noticed by her parents actually to put hair in her mouth and swallow it. This was observed occasionally in her up to her tenth year, but since that time it was thought that the habit had been discontinued and forgotten. She had always eaten heartily and digestion had been apparently normal until about one year prior to the present illness, when occasional attacks of stomach disturbance began, which were evidenced by stomach-ache, belching of gas, fetid breath, etc. These attacks, however, were not so frequent or so severe as to impress the parents as unusual.

Present Illness.—This began on the morning of July 19 with stomach-ache which was temporarily relieved by bowel action. Attacks of abdominal pain recurred during the day and night. She abstained from food during this time and there was no vomiting. Early the next morning, an attack of pain was followed by vomiting of bile and a bowel movement. Castor oil was administered but was rejected. The father, while examining the abdomen at this time, discovered the presence of a large sausage-shaped tumor which occupied the area between the ensiform cartilage and the umbilicus and extended crosswise from the cardiac area of the stomach to the region of the pylorus. The tumor on palpation was movable and tender. Examination of the lower abdomen elicited some tenderness over the appendix but otherwise was negative. The nature of the mass was a matter of doubt until a tuft of hair vomited a few hours later recalled to the father's mind the habit of hair-eating, and at once suggested the diagnosis of hair accumulation in the stomach. Dr. L. F. O'Neill, of this city, who saw her in consultation, concurred in the diagnosis. Two more attacks of pain and vomiting occurred during the second night. There was no disturbance of temperature or pulse. I examined the patient for the first time on the morning of July 21, having been called with regard to an operation. The findings previously described, together with the history, seemed to make the diagnosis clear.

First Operation.—This was performed at the Auburn City Hospital, July 21. A midline incision above the umbilicus exposed the stomach, which was seen to be the container of the mass. An incision about 3 inches in length was then made through the anterior wall of the stomach near the cardiac end, and through this a mass of firmly packed hair mixed with food particles and mucus was extracted. The hair tumor, which completely filled the cavity of the stomach and had adapted its form to the contour of the greater and lesser curvatures, weighed on removal 15 ounces. It measured 7¾ inches in length, 2½ inches in diameter, and 7 inches in circumference. The stomach incision was closed by three layers of continuous sutures, catgut in the mucous and muscular coats and linen in the peritoneal. The appendix was examined through the same incision, found to be thickened and injected, and was removed.

The patient, at the conclusion of the operation, was in good condition, and continued so for the next thirty-six hours. During this time two bowel movements occurred, one spontaneously and one by enema. About 6 p. m. July 22 she vomited nearly a quart of bile-stained fluid, and at 9:30 a like quantity of similar fluid. High enemas during the night resulted in free expulsion of gas with some fecal matter. No further vomiting occurred until 11:15 the morning of July 23, when, after the administration of 2 drams of calcined magnesia, she again vomited about a quart of bile-colored fluid. Castor oil was given an hour later and was retained for nearly six hours, when vomiting of about 8 ounces of bile-colored material mixed with oil occurred. After two further recurrences of vomiting and with distention of the abdomen beginning, it became evident that we had to deal with some form of ileus and that an exploration was indicated.

Second Operation.—The abdomen was opened through the original incision, at 5 a. m., July 24. As the patient seemed physically depressed an intravenous transfusion of normal saline solution was given during the operation. The seat of the gastrotomy was inspected and found satisfactory. No obstruction was found in the pylorus or duodenum, but a firm, movable mass was discovered in the ileum from which a firm mat of hair measuring 3 inches in length and completely occupying the lumen of the bowel was extracted after enterotomy.

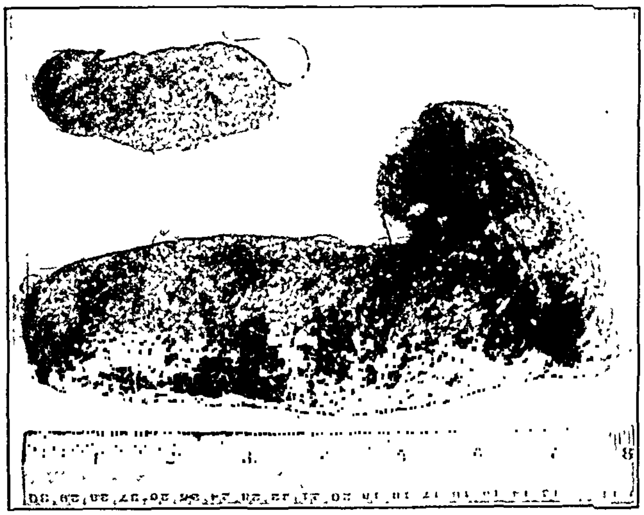
Postoperative History.—The patient showed some evidences of shock, but reacted promptly. No further vomiting occurred. The bowels moved freely during the first twenty-four hours succeeding the operation. Liquid food was begun at the end of eighteen hours and was well borne. With the exception of some fat necrosis in the line of the incision, the convalescence was uneventful. She was removed from the hospital to her home on the eighth day following admission. Since recovery from the operation she has been free from stomach symptoms and has gained 10 pounds in weight.

The presence of a hair-ball, hair-tumor or trichobezoar, as it is variously termed, in the human stomach, though infrequent, has ceased to be a very rare condition, over seventy cases having been reported in the literature. These reports include hair-tumors found throughout the gastro-intestinal tract at necropsy as well as in operations. Desiring to isolate the cases disclosed by operations, I have reviewed this literature and have been able to collect forty-one cases. Of these, thirty-five were gastrotomies for hair accumulations, which in some instances were prolonged into the duodenum; four were enterotomies or intestinal resections, in which one or more hair-balls were found in the ileum, while in two only both gastrotomy and enterotomy were performed in the same patient for separate hair-tumors, and in both instances the operations were performed at different times.

---

* Read by title before the Medical Association of Central New York, at Auburn, Oct. 30, 1913

The habit of hair-swallowing appears to be practically confined to females. Of the forty-one cases with operation, all occurred in either girls or young women, the youngest[1] being 7, and the oldest[2] 37. In most instances, where a history was obtainable, the habit had existed from early childhood and had been continued over a period of several years, in one case,[3] thirteen years. The greater number have preferred their own hair, either pulling it out and swallowing it, or chewing the ends of braids or curls, and occasionally swallowing in addition such articles as bits of string, cotton, wool, etc., which have formed a nucleus for the hair tumor. In only two cases has hair from a foreign source been recorded: one patient,[4] a woman aged 30, a spinner of cow's hair, was in the habit of moistening her finger with the tongue and thus swallowed enough to form a spherical hair-ball in the stomach weighing about 4 ounces; the other patient,[2] a woman aged 37, a brush-maker by trade, ate the bristles used in making the brushes, and the hair-tumor found was composed of this material.



Smaller object, in upper left-hand corner, hair-ball removed from ileum. Large mass below, hair-ball removed from stomach.

It is interesting to note that this peculiar habit has not as a rule been associated with mental enfeeblement, insanity or inebriety, but in the vast majority of cases occurred in persons otherwise quite normal. In a few cases a motive has been given in explanation of the practice. For example: Knowsley Thornton's patient[5] had for years been in the habit of "eating the combings of her hair and her sewing-cotton ends to clean her tongue"; Schönborn's patient[6] swallowed hers "to make her voice clear"; Jacobson's, because she liked the tickling sensation of the hair in its passage to the stomach.[7] In only three instances in this series has mention been made of any mental abnormality. One,[8] a girl of 16, was said to have always been hysterical; another,[9] aged 22, ate hair during delirium following an attack of grip; a third[10] occurred in a pregnant woman of 22, but there is no clear history to show that she had not eaten hair before her pregnancy.

The most frequent location of these hair-tumors is the stomach. It is relatively rare for them to be found in the bowel. In only six of the forty-one operations were hair-balls found in the intestinal tract. The tumor usually consists of a large accumulation of hair of varying length, firmly matted into a hard mass, which completely fills the cavity of the stomach, and is shaped by its walls into an exact cast of the organ. The general contour of these hair-balls of the stomach corresponds closely to the shape of the letter J, which reproduces the normal stomach outline as demonstrated by the Roentgen ray. In two cases,[2, 11] three distinct hair-tumors were found in the stomach, the separate masses adjoining each other by smoothly faceted surfaces. The hair-masses are not infrequently provided with processes which extend into either the duodenum or esophagus or both. Prolongation of the tumor into the duodenum occurred in seven of the cases reported. Just why more tufts of hair, which must be ingested in small quantities at a time, do not pass through into the bowel is not clear. One assumption is that the individual bits of hair reaching the stomach are caught in the mucous folds and thus retained, and that the subsequent additions gradually attach themselves to the primary nucleus in the slow formation of the mass. Hair-balls of the stomach often reach large proportions. The largest in this series is reported by L. Storey[12] as weighing 2½ pounds, but there are cases on record[13] in which the hair-mass weighed 4 pounds and over. The hair is usually mixed with food particles and is separated from the stomach-wall by a layer of mucus. From the weight of the contained mass the stomach-walls become hypertrophied, and the organ is frequently dilated and displaced. Practically all observers emphasize the mobility of the mass or the stomach itself. Langhaus[14] describes finding on the surface of the stomach whitish striae, due to distention, and resembling the striae of pregnancy. The mucosa seems to suffer the least, although small ulcers and even perforations have been noted in some of the necropsies.[15]

The symptomatology of hair-balls is far from characteristic and presents a wide range of variations. The only constant evidence of these masses in the stomach is the presence of a hard tumor in the upper abdomen.

which has been variously described as cucumber-shaped, sausage-shaped, oblong or spherical, usually movable. and only slightly tender on palpation. In exceptional instances there have been no manifestations whatever on the part of the stomach. In Bruce's case,[10] in a pregnant woman of 26, a hard swelling, which gave no symptoms, was discovered in the upper abdomen two months prior to childbirth. Twin pregnancy was suspected. The persistence of the tumor after delivery led to an exploratory operation which disclosed a hair-ball of the stomach. The gastric symptoms vary in degree from mild digestive disturbance with dull aching in the stomach, often noticed over a period of months or years without seriously affecting the general health, to repeated severe attacks of colicky pain and vomiting. The pain and vomiting, as a rule, occur after meals, and when occurring over a long period result in loss of weight and strength from inanition. In Jacobson's case,[7] that of a girl of 11, the pains occurred almost entirely at night, and she frequently vomited frothy mucus, but no food. These symptoms began over two years before the operation. During this time she lost strength and became very nervous. In some cases constipation had been persistent, while in others there have been frequent attacks of diarrhea. Occasionally small masses of hair have been vomited or passed by bowel, and this occurrence has led to a correct diagnosis. In the case reported by Ranzi,[16] in a girl of 20, an attack of acute intestinal obstruction occurred four years before operation. This was relieved by high enemas, which brought away masses of hair. Two years later the patient began to have pain in the stomach, which increased during a period of two years, when an operation relieved her of a hair-ball of the stomach weighing over a pound. Of the six patients with hair-ball in the ileum, four were operated on because of symptoms of complete intestinal obstruction, the other two because of a mass in the abdomen associated with pain and vomiting. One[17] of these was thought to be tuberculous peritonitis, the other[18] a malignant tumor of the small intestine.

In considering the histories of many of the cases, together with the size of the hair-tumor removed at operation, nearly all being described as completely filling the cavity of the stomach, it would seem probable that these large masses often remain in the stomach for long periods, months or years, without producing marked symptoms or materially interfering with the health of the individual. The question naturally arises, What determines finally the onset of acute symptoms which calls attention to the tumor and demands operation? In my case, the presence of the hair-ball in the ileum was thought to be responsible for the pain and vomiting instead of the tumor in the stomach; but in other cases the same symptoms have developed without any intestinal mass to explain them. The only theory advanced is that the stomach normally is exceedingly tolerant of foreign bodies, but that Nature rebels when the limit of tolerance is finally reached.

The difficulty of diagnosis in these cases is attested by the fact that of the forty-one cases in which an operation was performed, in only nine was a correct diagnosis made before operation. In eighteen of the cases no diagnosis was made and the exploratory laparotomy was on account of the presence of a tumor. In the remaining cases, various conditions were suspected, such as floating kidney, movable spleen, omental or hydatid cyst, tuberculous peritonitis, malignant growth, and in one case, already mentioned, the hair-tumor was supposed to be a twin pregnancy. In the cases in which a correct diagnosis was made before operation, a history of the habit of hair-swallowing had been obtained, or hair had been either vomited or passed by bowel. For the most part, the existence of the trichophagia was discovered after operation, the patients having previously denied it. In one instance reported by Rehorn,[19] a girl of 18 persistently denied ever having swallowed her own or other hair even after a hair-ball, weighing nearly 10 ounces, had been removed from her stomach.

The use of the Roentgen ray in the diagnosis of hair-ball of the stomach has only recently been emphasized by C. Thurstan Holland of Liverpool, England, in an article[11] reporting the case of a young woman of 29, who was admitted to the Royal Infirmary with a large hard tumor of the upper abdomen, but without any definite history. As the woman could not swallow anything in the nature of thick food, she was given a mixture of barium sulphate in milk and a roentgenogram was taken immediately afterward. This showed the distinct outline of three closely adjoining masses completely filling the cavity of the stomach. Operation later recovered three large hair-balls. Holland believes his to be the first description of the Roentgen-ray appearances in such a case. In one other report[20] mention of a roentgenogram is made, but in this case it did not lead to a correct diagnosis.

The operative treatment of hair-ball of the stomach has been attended by signal success. In the thirty-five gastrotomies reported, not a single fatality has occurred. Only two cases[18, 21] in the series resulted in death, and in these operations were done on nearly moribund children suffering from advanced intestinal obstruction due to hair accumulations in the ileum.

The two cases which at all parallel the one that I report are of interest in this connection. Bell's case[22] was that of a bright, intelligent girl of 12, who for nearly two years had attacks of vomiting, diarrhea and abdominal pain. The vomitus consisted mainly of frothy mucus, with at times particles of food. Six months prior to operation she had a very severe attack of vomiting and diarrhea, when a mass was felt in the abdomen, which was thought to be an abscess of the liver. The history showed that when she was 3 years of age she had a habit of breaking her hair with the fingers and that some difficulty was experienced in overcoming the habit. A diagnosis of probable hair-ball was made. Gastrotomy was performed and a large hair-cast of the stomach, together with a detached mass in the duodenum, was removed. At a second operation a hair-ball of the intestine, 8 inches in length, was extracted. At a fourth operation a section of the small intestine was found riddled with openings, and 2 inches of the intestine were resected. Other perforations developed and it was necessary again to resect a portion of the bowel, when a Murphy button was used, which she passed. Six months after her admission to the hospital, after undergoing eleven operations, she was said to be "on the high road to recovery."

Scott-Turner's case[23] was in a woman, aged 29, who had been suffering for several years from intestinal colic with symptoms of intestinal occlusion. Operation disclosed an obstructing hair-ball in the ileum. Four weeks later symptoms of pyloric stenosis supervened and the material vomited contained hair. Gastrotomy was performed and a hair-ball was found impacted in the pylorus. Recovery ensued.

In both these cases of multiple hair-balls involving the stomach and intestine, the presence of another mass was unsuspected at the first operation. These experiences, together with mine, indicate that a thorough examination of the entire gastro-intestinal tract should be made before closure of the abdomen in every operation for hair-ball.

The other cases reported in the literature are nearly all taken from necropsy records, death having ensued from inanition, perforation or obstruction, the diagnosis being made post mortem. With increasing familiarity with this class of tumors should come an earlier recognition of an operable condition and a steady decrease in such a heavy mortality.

CHOREA

WITH REPORT OF TWO CASES IN WHICH STREPTOCOCCUS VIRIDANS WAS FOUND IN THE BLOOD *

JOHN H. RICHARDS, M.D.
NEW YORK

Ever since Roger in 1866 classed rheumatism, chorea and endocarditis as manifestations of the same pathologic entity there has been much controversy as to the etiology. A review of the literature leaves no doubt that there is a relationship between these diseases. Sturges, Peacock, Owen, Wollenberg, Osler, Hughes, See, Brown, Batton, Meyer, Bright, Garrod, Herringham, Mackenzie and many others have written on this relationship, and have given statistics showing a relationship in from 15 to 80 per cent. of all cases. There are those who conclude that no definite relationship can be established, and at the other extreme there are those who, like Roger, assert that acute rheumatism, chorea and endocarditis are but different manifestations of the same underlying disease. Of late Butler, Hoskins, Anderson and MacAlister have published studies on this relationship. In the main this relationship is based on clinical findings, such as the very frequent association of rheumatism, chorea and endocarditis.

Of late years more attention has been paid to the bacteriology of chorea. To quote from Church:

> Dana found a coccus in a case of chorea in which there was a leptomeningitis of the brain and of the upper part of the cord. In a severe case of chorea and rheumatic endocarditis Triboulet found Achalme's bacillus. In two cases Apert found Triboulet's coccus. Westphall, Wassermann, and Malkoff found a coccus in the brain of one patient. Poynton and Paine isolated a similar coccus in several cases of chorea. In three cases Beaton and Walker found the same coccus.

Camisa and Guervicr have independently reported the finding of cocci in the blood of chorea patients. In their reports the cultural characteristics are not fully given, but so far as given there is no difference between their findings and those of Poynton and Paine.

In January of this year Collins reported a case of chorea as cured by treatment with an autogenous vaccine prepared from a coccus obtained by lumbar puncture.

The following cases are reported, one in Bellevue Hospital from the service of W. Gilman Thompson, and one in private practice.

Case 1.—*History.*—On admission of the patient, a woman, aged 20, to the hospital, her speech was so inarticulate that it was difficult to obtain a history. The following was learned from visitors: The father and mother were dead—cause not known. The patient had no brothers or sisters. There was no history of any of the common diseases of childhood. The patient had not had typhoid, malaria, rheumatism, tonsillitis, torticollis or chorea. The patient was unmarried, and had one child 4 months old. So far as could be ascertained the patient's pregnancy was normal excepting for occasional vomiting. There was no history of venereal disease.

About April 1, 1913, the patient's right wrist became painful, swollen and hot. At the same time speech became inarticulate. Also she began to have involuntary spasmodic movements, especially marked in the head, but occurring throughout the body. The pain in the right wrist lasted about two days, after which the small joints of the right hand became involved. This did not clear up. On April 29, the left hand became involved in all joints. The patient was unable to sleep on account of the jactitation.

Physical Examination.—This revealed an acute multiple arthritis, a chronic valvular endocarditis, and pyorrhea alveolaris. Otherwise it was negative. There were no petechiae. The temperature on admission was 101 F. and gradually rose to 106 F. at the time of death three days later. The pulse and respirations were commensurate with the temperature.

Blood-Culture.—April 29, 1913, a culture of blood from a vein was made in North's agar at 43 C. (109.4 F.) by pouring five plates. The temperature of the incubator was 37 C. (98.6 F.). No growth appeared on any plate for eight days, when all showed colonies of the following characters:

1. They were uniformly distributed on the plates (from five to nineteen colonies to a plate) and formed below the surface of the medium.
2. The colonies and the immediate vicinity were green. In growths without blood this color did not appear.
3. The colonies were pin-point in size and did not greatly enlarge on further incubation.
4. There was no hemolysis.
5. When grown in broth, chains of eight to ten were formed. Each coccus was very small, and sometimes slightly elongated. When grown in bile medium the cocci were not dissolved. Litmus milk showed acid production in three days with coagulation, but no peptonization. Acid was produced in the following carbohydrate mediums: lactose, dextrose, arabinose, raffinose and saccharose, but not in dextrin, mannite and salicin. Inulin was not coagulated after ten days. (These cultural methods were suggested by Dr. Thro, who will publish his methods in detail later.)
6. The coccus retained the Gram stain.
7. There were no capsules.

Control.—The blood from a convalescent typhoid patient was used as control, and all plates remained sterile. The bloods were taken within a few minutes of each other and were treated exactly alike.

May 1, 1913, another specimen of blood was taken, controlled and treated in the same manner. The same coccus was again isolated and treated to the same cultural tests with the same results.

Case 2 (from private practice).—*History.*—The patient was a girl aged 9. The father was alive and well. The mother had an acute rheumatic fever twice, followed by chronic endocarditis. The patient had acute rheumatic fever when 3 years old, complicated by endocarditis, and had had tonsillitis frequently. In December, 1912, the patient's heart lost compensation following a severe attack of tonsillitis.

---

* From the department of Clinical Pathology, Cornell University Medical College.

* This article is abbreviated in The Journal by omission of the bibliography. It appears in full in the author's reprints, a copy of which will be sent by him on receipt of an addressed stamped envelope.

On this account she was kept in bed and given a milk diet. At this time there was no fever. Later, in May, 1913, however, a low grade of fever developed, and in a few days a well-marked chorea. There was no joint involvement. The heart at this time was fairly well compensating. With the development of the chorea the child became stupid and the jactitation of her arms and face so marked that she had very little sleep.

Blood-Culture.—May 30, 1913, a culture of blood from a vein was made in North's agar, poured in five plates. The temperature of the incubator was 37 C. No growth appeared on any plate for six days, when four plates showed colonies (one remained sterile) of the same character as the colonies in the preceding case, excepting that acid was not produced in saccharose. The staining characters were the same as in Case 1. The control was accomplished in the same manner as in Case 1.

June 15, 1913, the coccus grown from Case 2 was used in the preparation of an antigen and the patient's serum was tested against it with positive result for complement fixation. The serum from a convalescent typhoid was used as control, and the test was negative. The technic was that of Schwartz and MacNeil for gonococcus and of Hastings for streptococcus. A second test was made with stock-mixed antigen prepared from two strains of *Streptococcus viridans* isolated from the blood of two patients with chronic infectious endocarditis. The test was positive.

June 20, 1913, cultures were made from the crypts of the tonsils in Case 2 and a coccus culturally identical with the coccus found in the blood was found. An antigen was made from this coccus and tested against the patient's serum. The result was positive. The blood was again taken from the vein of the patient as before. The same coccus was isolated. This time it was obtained on all plates. The complement-fixation tests as done on June 15, 1913, were repeated with positive results.

A study of these cases shows that the organism found in the blood in the two cases in no way differs from the description of the *Micrococcus rheumaticus* of Poynton and Paine, but on the other hand it is culturally identical with the description of the green-producing streptococcus of Schottmueller. The fact that the coccus of Schottmueller and the coccus of Poynton and Paine are culturally identical was observed by Hastings in 1912, and later worked out by Thro at the suggestion of Hastings.

Undoubtedly the coccus isolated by Dana and others mentioned before is identical with the coccus found in the two cases reported. The number of cases, however, is too small to form definite opinions as to the etiology of chorea. Certainly more work along these lines is indicated. That the coccus found in the blood is associated with endocarditis there is no doubt; but that it is the etiologic factor sine qua non in chorea is not proved.

The peculiarities of the coccus isolated are as follows:

1. It is of very slow growth. Sometimes the *Streptococcus viridans* does not appear in the original blood-culture for twelve days.
2. Green is produced on blood-agar plates.
3. It is of relatively slight toxicity.
4. It is not dissolved by bile as is the pneumococcus.
5. It does not peptonize milk as does *Micrococcus zymogenes*.

Encouraging the Health Department.—Every thoughtful citizen should know what work the health department is doing and the extent of protection from disease that is being given to him and to those dear to him. Such interest will in itself insure more efficient work, for the health department needs the moral support, the approval and at times the cooperation of all intelligent citizens.—John W. Trask, *Pub. Health Rep.*

RELATION OF THE PATHOLOGY AND THE CLINICAL SYMPTOMS OF SIMPLE AND EXOPHTHALMIC GOITER *

LOUIS B. WILSON, M.D.
Director of Laboratories, Mayo Clinic
ROCHESTER, MINN.

I have recently reviewed in fixed tissues the pathology, both gross and microscopic, of all the thyroid glands now in the laboratories of the Mayo clinic which have been removed from patients on the "exophthalmic goiter" list from Jan. 1, 1905, to Jan. 1, 1912, a total of 1,208 exophthalmic thyroids. My report on these specimens has been published elsewhere.[1] I have also examined, in the same manner, all the thyroids now in the laboratory removed from patients on the clinical "simple goiter" list from Jan. 1, 1905, to June 1, 1913, a total of 2,356 simple goiters.

The clinical grouping of these cases is not so simple as would be indicated by the two lists, "exophthalmic" and "simple." While the lists express their clinical grouping as the cases would ordinarily be arranged in most clinics, Plummer[2] has recently differentiated the goiters into three clinical groups: A, true exophthalmics distinguished by relatively rapid development, exophthalmos, etc.; B, toxic non-exophthalmics distinguished from the preceding by slow development, absence of exophthalmos, etc.; and C, non-toxic goiters, distinguished from both of the preceding by entire absence of toxic symptoms. It is therefore necessary to remember that in our "exophthalmic goiter" list, 79 per cent. are true exophthalmics, 21 per cent. are toxic non-exophthalmics and in the "simple goiter" list, 17 per cent. are toxic non-exophthalmics and 83 per cent. are non-toxic.

Each acinus of the thyroid gland can take on changes unlike those found within those adjoining it. Hence it is necessary in attempting to determine the dominant pathologic condition of the gland for purposes of classification to make a detailed analysis from the study of sections from many areas and finally to summarize the tabulated record of the observations. Such a summary can best be made from a tabulation in which numerical equivalents are used wherever possible to indicate degrees, amounts, etc. Without going into the minutiae of the specimens which I have examined, I wish to present herewith a broad summary of the results.

An examination of the accompanying table will reveal the following salient points:

1. Practically all cases of clinically true exophthalmic goiter show marked primary hypertrophy and hyperplasia of the parenchyma of the thyroid gland. Furthermore, as I have shown elsewhere,[3] the clinical stage of development of the disease is paralleled by the stage of development of the pathologic condition in sufficiently marked degree that one may estimate the clinical condition from the pathologic examination with about 80 per cent. of accuracy. The degree of severity of the clinical condition is similarly paralleled by the pathologic condition of the gland. The relationship between hypertrophy and hyperplasia of the thyroid gland and the clinical symptoms of true exophthalmic goiter is remarkably constant.

---

[2] Plummer: Am. Jour. Med. Sc., 1913.

[3] Am. Jour. Med. Sc., 1913, and New York Med. Rec., 1913.

2. While mild degrees of hypertrophy and hyperplasia within physiologic limits may be present in the thyroid gland, particularly in the young and during pregnancy, yet the absence of this condition in the thyroids of adults coming to operation for toxic non-exophthalmic and non-toxic goiters is most striking. Without making any allowance for either clinical or pathologic errors of diagnosis, less than 1 per cent. of all cases coming to operation for goiter show any considerable primary hypertrophy and hyperplasia of the parenchyma of the thyroid except as associated with clinical symptoms of true exophthalmic goiter.

3. Eleven per cent. of *all the thyroids on the "simple goiter"* list showed as their principal pathologic change a secondary regeneration of atrophic parenchyma. This secondary regeneration of atrophic parenchyma is marked by the development, usually on one side of an acinus, of multiple, small, new acini composed of embryonic or cuboidal epithelium surrounding a minute cavity in which is found a very small amount of usually quite densely staining colloid. This newly developed tissue may extend out into the acinus in an irregular mass which can usually be readily distinguished from the papillae of a primary hypertrophy by the small size of its cells as compared with the very large columnar cells which mark the latter. These secondary regenerations are almost invariably recent enlargements of old "colloid goiters" whose primary atrophy must have occurred years before.

4. Besides the 11 per cent. of glands of this type noted on the "exophthalmic goiter" list, 9 per cent. of the glands on the "simple goiter" list were of the same type. All the thyroids from patients on the "exophthalmic goiter" list which showed secondary regeneration were from patients whose clinical symptoms were marked toxic non-exophthalmic. Similarly, about half of the thyroids on the "simple goiter" list showing secondary regeneration were from patients who clinically gave symptoms of toxic non-exophthalmic goiter. Thus in all, above 75 per cent. of the thyroids showing secondary regeneration of atrophic parenchyma were associated clinically with symptoms of chronic toxic non-exophthalmic goiter. It would appear from this that the pathologist is safe in saying that a colloid goiter which presents a large amount of regeneration is from a patient presenting chronic toxic non-exophthalmic symptoms. It must be remembered, however, that in a large number of the glands the process is too indefinite to permit the pathologist correctly to estimate the clinical condition of the patient.

5. Ten per cent. of the thyroids from patients on the "exophthalmic goiter" list were composed principally of encapsulated adenomas. All of these were from patients with clinically toxic non-exophthalmic goiter.

6. Forty-five per cent. of the thyroids from patients on the "simple goiter" list were composed principally of encapsulated adenomas. More than half of these are distinctly of the so-called fetal adenoma type, that is, they consist of acini made up of small cuboidal or embryonic epithelium in spheroidal or columnar groups without lumina. The term "fetal adenoma" is somewhat misleading since the thyroid in late fetal life is made up almost entirely of acini with definite lumina.

The smaller portion of the adenomas contains so many acini with lumina that one is not warranted in classifying them at all as fetal and I have consequently grouped them as adult adenomas.

7. Less than 0.5 per cent. of the thyroids from patients on the "exophthalmic goiter" list but more than 44 *per cent. of the thyroids from patients on the "simple goiter"* list consist principally of groups of dilated acini filled with thick densely staining colloid material and lined with atrophic parenchyma. While many of these show varying amounts of stroma more or less segregating groups of acini, none of them have been placed in this class if they showed any considerable amount of definitely encapsulated tumors. While these partially encapsulated groups of acini may represent definite growth centers, it seems quite as probable that their partial segregation may have occurred from irregular development of the stroma after the beginning of the pathologic process. The terms "adenomatoses" and irregularly diffuse colloid thyroid may properly be applied to them.

CLASSIFICATION (IN PERCENTAGES) OF THE PRINCIPAL PATHOLOGIC CHANGES IN 3,564 THYROIDS REMOVED AT OPERATION FOR GOITER

1208 Thyroids from Patients on "Exophthalmic Goiter" List		Principal Pathologic Changes	2356 Thyroids from Patients on "Simple Goiter" List		
Clinically true exophthalmic goiter.	79%	Primary hypertrophy and hyperplasia of parenchyma.		0.6%	Clinically 17% toxic non-exophthalmic goiter, and 83% non-toxic goiter.
	(3%)	A Early.			
	(34%)	B Advanced.			
	(41%)	C Regressing.

		Malignant tumors.		1.5%	

"I Do Not Know."—While Maimonides could be so positive in his opinions with regard to a subject on which he felt competent to say something, he was extremely modest with regard to many of the great problems of medicine. He often uses the expression in his writings, "I do not see how to explain this matter." He quotes with approval from a rabbi of old who had counseled his students, "Teach thy tongue to say, 'I do not know.'" In this, of course, he has given us the best possible evidence of his largeness of mind and his capacity for making advance in knowledge. It is when men are ready to say, "I do not know," that progress becomes possible. It is very easy to rest in a conscious or unconscious pretense of knowledge that obscures the real question at issue. A great thinker who lived in the century in which Maimonides died, Roger Bacon, set down as one of the four principal obstacles to advance in knowledge—indeed, as *the* one of the four that hampered intellectual progress the most—the fact that men feared to say, "I do not know."—Walsh, Makers of Medicine.

THE IODIN CONTENT OF THE THYROID GLAND

WITH ESPECIAL REFERENCE TO THE PATHOLOGIC TYPES AND A REVIEW OF SOME EXPERIMENTAL WORK *

ERNEST V. SMITH, M.D.
Senior Assistant in Pathology

ASSISTED BY A. C. BRODERS, M.D.
Junior Assistant in Pathology, Mayo Clinic
ROCHESTER, MINN.

For many years it has been known that the normal thyroid contains a small amount of iodin in combination with a protein or albuminous substance.

The object of this paper is to present a study of the iodin content of toxic thyroids as observed in the normal and pathologic glands removed at necropsy and in the pathologic glands removed at operation in the Mayo clinic, and also to review some experimental work pertaining to the metabolic function of this gland.

The results of nearly 200 iodin determinations which have been made in the Mayo clinic agree in general with the results which have been obtained by others who have worked along this same line. Wherein our results differ from the usually accepted findings will be shown by a comparison of the data. The same method of determining the iodin content was used which Hunter[1] advocates and the precautions which he mentions in his original article on the subject were observed. In all these iodin determinations blank controls were run with each analysis, and every analysis represents the average of from 2 to 6 tests on the same gland. Every precaution was taken in the preparation of the desiccated thyroid. The glands were finely minced within a few minutes following their removal. When it was not desired to use the entire gland, representative parts were taken. These portions were dried to a constant weight and powdered finely enough to pass through an eighty-mesh sieve.

A brief outline of the Hunter method is as follows:

> One gram of desiccated thyroid gland is mixed in a nickel crucible of about 125 c.c. capacity, with 15 gm. of a mixture composed of 138 parts by weight of anhydrous potassium carbonate, 106 parts of anhydrous sodium carbonate and 75 parts potassium nitrate, and an additional 5 gm. of this fusion mixture spread evenly over the surface. The crucible is then heated over a free Bunsen flame until no further carbonization is observed; it is cooled and the friable residue dissolved in about 150 c.c. of distilled water. To this solution contained in an Erlenmeyer flask of about 500 c.c. capacity, is added approximately 50 c.c., or its equivalent, of fresh liquor sodae chlorinatae U. S. P. (containing 2.4 weight per cent. of chlorin). The mixture is then treated with enough phosphoric acid (1 volume of the 85 per cent. syrup and 1 volume of water), to produce a marked yellow tint of free chlorin, an additional 10 c.c. of the phosphoric acid is then added and the contents of the flask boiled for about one-half hour or until the volume has been reduced to about 150 c.c. The liquid is cooled, 10 c.c. of 1 per cent. aqueous potassium iodid solution is added and the liberated iodin titrated with two-hundredth-normal sodium thiosulphate, adding starch paste as the indicator just before the end of the reaction. The two-hundredth-normal sodium thiosulphate may be made by diluting 25 c.c. of exactly tenth-normal thiosulphate to 500 c.c.; it changes strength rapidly and should be prepared fresh at each time determinations are made. One cubic centimeter of two-hundredth-normal thiosulphate corresponds to 0.0001058 gm. iodin derived from the sample of thyroid used.

Usually it is true that the iodin content of the normal thyroid is the greatest; the content of the colloid gland is less and that of the parenchymatous hypertrophic and hyperplastic gland is least per gram weight of dried gland. Roughly estimated, the normal thyroid will contain about 2.5 mg., the colloid gland about 1.5 mg. and the hyperplastic gland about 0.5 mg. of iodin per gram weight of dried gland.

An analysis of the iodin determinations which were made from 49 glands removed in the surgical treatment of hyperthyroidism is presented in the accompanying tables. The parenchymatous hypertrophic and hyperplastic glands are classified in three groups—A, B and C, A and B being those glands which show very marked hypertrophy and hyperplasia and C being those glands which show regression stages with a greater amount of more or less densely staining colloid.

This histologic classification is from that proposed by Wilson.[2] The chemical study was completed without a knowledge of the histologic classification in order that there might be no possibility of a biased finding.

TABLE 1.—EXOPHTHALMIC GOITERS OF GROUPS A AND B (PARENCHYMATOUS HYPERTROPHY AND HYPERPLASIA) ON WHICH IODIN DETERMINATIONS WERE MADE*

Of. No.	Sex	Age	Dates of Ligations	Date of Operation	Weight	Amount	Density	Amt. of Iodin

75743	F	29	11/11/12	11/15/12	75	1	1	0.48
75733	F	31		11/12/12	50	2	2	0.92

* The dagger (†) in the column of official numbers designates the specimen belonging to Group A; the others belong to Group B.

As will be seen from a study of Tables 1 and 2, twenty of the forty-nine glands of the parenchymatous hypertrophic and hyperplastic class are of the Groups A and B (early and advanced parenchymatous hypertrophy and hyperplasia). The average iodin content of these twenty glands is 0.54 mg. per gram weight of dried gland. The smallest amount of iodin found in any of these markedly hyperplastic glands was 0.12 mg. per gram weight of dried gland. The largest amount was 1.27 mg. There were twenty-nine glands of the hyperplastic type which histologically are classified in group C (regressing parenchymatous hypertrophy and hyperplasia). The average iodin content for this group is 1.52 mg. of iodin per gram weight of dried gland. The smallest amount of iodin found in any gland of this group was 0.44 mg. per gram of dried gland, and the largest amount was 4.79 mg. It is among the glands found in this group that our findings differ from the results as recorded by Marine and Lenhart[3] working along this same line. From Table 2, it is noted that there are three cases in which the iodin content was found to be well above that which is generally accepted to be the average amount found in the normal thyroid, and there are sixteen cases which show an amount above 1.30 mg., which is usually accepted as the minimum for normal thyroids. In other words, about 33 per cent. of hyperplastic glands show a high iodin content.

---

Many of the glands analyzed for iodin were from patients who had a ligation previous to the time of removal of the gland. The question naturally arises, Did the ligation affect the iodin content? From the table showing thyroids of groups A and B—those representing early and marked hypertrophy and hyperplasia—it is noted that there are only four patients in whom ligation was not done previous to operation. The average iodin content from these four patients is found to be 0.77 mg. The average iodin content for the sixteen patients in whom ligation had been done shows 0.49 mg. The glands of these groups then show a loss in the iodin content following ligation.

75496	M	30	11/8/12		11/15/12	90	4	3	1.94
76959	F	35			12/11/12	65	2	3	1.87
77136	F	34	12/14/12		12/20/12	50	3	2	1.09

The same condition is found to be true in the glands listed in Group C. There are twenty-nine glands of this group on which iodin determinations have been made. Only three from this group have not had ligations previous to removal. The average iodin content of these three glands is found to be 1.68 mg., while the content of the twenty-six glands of this group which had a previous ligation show an average iodin content of 1.50 mg. When the iodin content of the whole class of hyperplastic glands is considered and the content of the nonligated glands compared to the content of those which have had a previous ligation, it is found that the average for the non-ligated glands is slightly below those which have been ligated.

It is our opinion, from a study of the preceding data, that ligation in the majority of cases slightly decreases the iodin content of hyperplastic glands. It is true that the averages of the non-ligated cases are computed from a small number. However it is significant that the results are similar in both groups of cases.

Does age play any part in the amount of iodin found in the hyperplastic gland? Ten patients who were between 17 and 30 years of age show an average iodin content of 1.02 mg. Ten patients who were all above 30 years of age show an average iodin content of 0.71 mg. It is evident from these figures that hyperplastic glands of patients from 30 to 50 years of age contain less iodin per gram weight than do those glands from patients of 15 to 25 years of age.

The size of the hyperplastic gland also seems to bear some relation to the amount of iodin per gram weight of dried gland. The larger glands of group C are found to have less iodin per gram of dried gland than the smaller glands. An average of eleven of the larger glands of Group C show 1.37 mg. of iodin as compared with 1.59 mg., the average of eleven small glands. The same condition also exists in the case of glands of Groups A and B. Averages on eight large and a like number of small glands from these groups show the amount of iodin as 0.33 mg. in case of the large glands as compared to 0.56 mg. in case of small glands.

In considering the amount of iodin found in the thyroid, at least two factors regarding the nature of the colloid substance must be considered. The first factor of importance is the amount of colloid. The second factor is the density of the colloid. There are certain hyperplastic glands which have large acini, filled with a thin or watery secretion, which do not have so great an iodin content as some other glands whose acini may not be so large but whose secretion is denser. As a rule, the denser the secretion, the deeper it stains and the larger amount of iodin it contains.

The iodin determinations of seventeen simple colloid goiters classified in Group II (colloid thyroids) show an average iodin content of 1.84 mg. of iodin per gram weight of dried gland. The minimum amount found in any of the colloid glands was 0.41 mg. per gram weight and the maximum amount was 3.33 mg. These variations are about the same as those found by Marine and Lenhart,[3] except that both our maximum and minimum are slightly below what they found.

It is usually found that the pure fetal adenomas contain very small amounts of iodin. This is to be expected, as the colloid in such glands is small in amount and rarely of much density as shown by its staining reaction.

In connection with this work on the iodin content of the thyroid as found in pathologic specimens, I have carried out a series of experiments on dogs to determine to what extent the iodin content of their thyroids would be affected by the administration of the iodids and which form of medication would produce the greatest increase in iodin content.

Fourteen dogs have been used in these experiments. In selecting the dogs, endeavor was made to obtain dogs as near the same size and weight as possible. Previous to the time of beginning the experiments, they were kept under the same conditions as to housing and feeding. During the period of administration of iodids, the dogs were kept and fed under the same conditions. The methods of administration of iodids were as follows:

1. The painting of the U. S. P. tincture of iodin on the shaven skin.

2. The administration, by mouth with the food, of a one to one aqueous solution of potassium iodid in doses ranging from 15 to 30 drops each day.

3. The subcutaneous injection of from 20 to 45 drops of a one to one solution of potassium iodid diluted to 5 c.c., one injection each day.

Three dogs of the entire number were used as controls and to these no iodids were given. The determination of the iodin content of the thyroids removed from the three control dogs was 2.58 mg. of iodin per gram weight of dried gland. Five dogs were painted with the tincture of iodin and the average iodin content of these glands was 6.5 mg. per gram weight of dried gland. Three dogs had subcutaneous injections of potassium iodid. The average iodin content of their glands was 5.53 mg. Four dogs were given potassium iodid with their food. The average iodin content of their glands was 2.73 mg.

TABLE 3.—SHOWING THE STORAGE POWER OF THE THYROID GLANDS OF DOGS REGARDING IODIN

13	Tr. iodin painted...	16	8"x8"	11/20/12	10.18

It was noted from these methods of administration that the external application of the tincture of iodin caused the greatest average increase of the iodin content of the gland. It was further noted that the dogs, receiving the subcutaneous injection of the iodid lost weight very rapidly. While these dogs did not store up so much iodin in their thyroids as the dogs which were painted with the tincture, yet they seemed to experience a much greater systemic effect from the drug. When the potassium iodid was fed with the food, it caused very little increase in the iodin content.

Pathologists doing post-mortems often see the final picture in the most extreme cases of hyperthyroidism and it is from such cases and from a review of all the cases which have come to necropsy that three most constant conditions are encountered.

1. The extreme emaciation of all patients dying from hyperthyroidism is mentioned. That the iodids when given in large doses over a period of time do cause a great loss in body weight there is no doubt. The same therapeutic fact is taken advantage of by manufacturers of proprietary antifat remedies and preparations of thyroid are greatly used by them.

2. The general appearance which the intestinal tract presents is noted, i. e., the contracted intestines which have a congested appearance with the mesenteric vessels engorged with blood; such a condition may be produced by chronic poisoning with any of the metallic poisons. A similar condition has been noted in animals which we have sacrificed after chronic iodin poisoning.

3. The microscopic picture of a section of the liver. Almost invariably, the section shows fatty degeneration (lipoid changes) of various degree. This lipoid change of the liver is the result of some chronic intoxication. The question naturally arises, What is the nature of the poison producing it? It is well known that such fatty changes occur in many chronic diseases. Tuberculosis and chronic alcoholism might be cited as examples in which such a change frequently occurs. It has been known for many years that phosphorus will produce a lipoid change of the liver when given in toxic doses. Will iodin also produce such a lipoid change when so given? Cushny[4] says that iodin, like phosphorus, does produce a fatty degeneration (or lipoid change) in the liver and other organs. Further, he says that thyroid likewise produces a fatty degeneration in various organs when given in excessive doses to the point of poisoning.

A poison known as acetonitrile has been used by Hunt[5] as a measure to determine thyroid activity. He found that by feeding white mice with cracker cakes containing desiccated thyroid, *their resistance to acetonitrile poisoning* was increased.

Following Hunt's plan, I have carried out a series of experiments on white mice, feeding them with the desiccated thyroid of parenchymatous hypertrophic and hyperplastic and colloid glands removed at operation. Cracker cakes were used as a food for the controls and cracker cakes, to which the fresh desiccated glands were added, were used as a food for experiment. It was found that those mice which received the cracker cakes containing the desiccated parenchymatous hypertrophic and hyperplastic glands have a slightly greater resistance to acetonitrile than those mice which were fed on the plain cracker cakes. Those mice fed with cracker cakes to which the desiccated colloid goiters had been added had a higher resistance than either the controls or those fed with hyperplastic glands. In neither group was it possible to produce a resistance equal to that produced by Reid Hunt when he fed the desiccated commercial thyroid made from the sheep.

By painting the tails of the mice with tincture of iodin on three or four successive days, however, it was found that an increase in resistance to acetonitril poisoning was obtained equal to and, in many cases, greater than that obtained by feeding with desiccated thyroids. When the painting is carried beyond the seventh or eighth day, the degree of resistance becomes less positive due to the poisonous effects produced by the iodin.

Regarding chronic iodism in man, the United States Dispensatory[6] gives the following symptoms:

> Even in medicinal doses, it sometimes causes alarming symptoms such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse and, finally, progressive emaciation if the medicine be not laid aside. *Absorption of the mamma and wasting* of the testicle have been reported as caused by the long-continued use of the drug.

It will be noted that many of the symptoms present in chronic iodism correspond very closely to those of hyperthyroidism.

Clinical experience regarding the use of iodids in simple goiter demonstrates that there is a certain class of patients who often receive great benefit from the administration of the iodids in some form. On the contrary, cautious physicians empirically hesitate to prescribe large doses of the iodids to patients with severe cases of hyperthyroidism *for fear of increasing the* symptoms. It is a well-known fact that some individuals are very susceptible to the iodids. Berg[7] has reported several cases of patients receiving full doses of iodids, who rather suddenly developed the symptoms usually noted in hyperthyroidism. Physicians writing in the early part of the last century, who, in many things, were very close observers, recognized that there were cases of "bronchocele" that were made much worse by large doses of iodids. The following paragraph was written before the time that the train of symptoms known to-day as hyperthyroidism was generally recognized:[8]

[6] U. S. Dispensatory, Ed. 19, p. 667.
[7] Berg: Deutsch. med. Wchnschr., 1911, xxxvii, 300.

> After a few weeks' skilful administration of potassium iodid the external swelling will gradually disappear. Should the patient, while under a course of it, experience any considerable quickening of the pulse, a rapid loss of flesh, palpitation of the heart, a dry cough, restlessness and want of sleep and, in certain cases, with an increase of appetite for food, though the swelling shall undergo diminution, it will be necessary to intermit the medicine for some days and afterwards resume the use of it when the health and safety of the patient will permit.

On the hypothesis that the symptoms of hyperthyroidism are those produced by chronic iodism, how may the physiology of the thyroid be explained? It is possible that one of the functions of the thyroid is the control of iodin metabolism and that it bears a relation to iodin which might be compared to the relation of the liver with glycogen. There may be conditions under which the thyroid fails in its control of this iodin metabolism, and the continued intake of iodin into the system from natural sources, without its being metabolized, produces the chronic poisoning.

That the thyroid does act as a storehouse to iodin has been demonstrated frequently. It seems possible that it is the iodin, which is not stored or metabolized by the thyroid, which produces the Basedow syndrome. It is more easily stored or metabolized when administered in the pure form than when given in a combined state. The activity of various desiccated thyroid preparations apparently depends on their iodin content. Both theoretically and practically they are the most active of the iodin preparations.

We continually receive from food and water and possibly air a certain amount of iodin in various forms. Seidell and Fenger[9] point out that in cattle, sheep and hogs there is a seasonal variation in the iodin content of the thyroid glands. Possibly such seasonal variations are from the food which they receive, their iodin content beginning to rise as soon as the pasture comes.

Kocher[10] has shown that patients suffering with Basedow's disease, when treated with iodids, excrete a larger proportion in the urine than do normal individuals. From this it may be inferred that they do not metabolize iodin to the extent the normal person does.

There are many things concerning the toxic goiter which we do not understand, but it may be possible that it is the faulty metabolism by the thyroid as much as the hypersecretion which acts in producing the symptoms known to-day as hyperthyroidism.

A COMPARATIVE STUDY OF THE EFFECTS ON BLOOD-PRESSURE OF THE EXTRACTS AND SERUMS OF EXOPHTHALMIC GOITER AND OF OTHER SUBSTANCES *

A. H. SANFORD, M.D.
AND
J. M. BLACKFORD, M.D.
ROCHESTER, MINN.

When injected intravenously into laboratory animals, extracts of most tissues show the presence of one or more substances with some depressor action. Rabbits and cats have been used for these experiments, but the dog is the animal best adapted for the purpose. By using an arterial cannula direct records of blood-pressure are obtained by means of the mercury manometer and the kymograph. It is observed also that with certain substances a marked fall in blood-pressure occurs on the first injection, but on the administration of a second dose a few minutes later a remarkable tolerance is revealed. The action of peptone on the blood and blood-pressure has been the subject of physiologic investigation for years. This substance causes a marked fall in blood-pressure with a subsequent tolerance to the same dose when injected intravenously.

Howell,[1] Jordan and Eyster,[2] Dixon and Halliburton,[3] and others, working with pineal extracts, have shown a fall in blood-pressure followed by a less marked effect on the second injection. A rise in blood-pressure followed by tolerance has been shown for the hypophysis by Howell,[1] and Lewis, Miller and Matthews.[4] There have been various conflicting results with the intravenous injections of extracts of the thyroid gland. We can confirm the results of Gley,[5] Schönborn[6] and others that in proper dosage there is a primary fall in blood-pressure and a less marked effect on second injections of extracts of goiters.

Brodie,[7] in his work with horse-serum injected into cats, noted a fall in blood-pressure with a subsequent tolerance. He noted further that the animal is protected by this first dose against the action of similar substances. He does not state, however, what his control substances were. Gley and Cleret[8] found that in a series of six patients suffering from exophthalmic goiter the serums of two caused a marked fall in blood-pressure in dogs, and a second dose of the same serums had little or no effect.

On the other hand, while cholin may cause a marked fall in blood-pressure when injected intravenously, it does not produce a tolerance. Halliburton[9] has shown by chemical analysis that cholin is abundant in extracts from brain-tissue and is the depressor substance. This is probably the substance causing lowering in pressure in extracts of any tissue in which proteolytic changes may have occurred. We believe that if the extract of a tissue shows the presence of a depressor substance without tolerance following, the presence of proteolytic change should be suspected. It would seem also that this proteolytic change begins in the tissues very soon; thus nothing but fresh extracts should be used.

In our work with the above-mentioned substances and other extracts of tissue, we may have gone a step farther than other investigators in that we have used a number of different substances in the same animal. It seems that the action of an extract producing tolerance to subsequent injections is more or less specific. The administration of an extract of another sort of tissue is followed by all the phenomena peculiar to that substance, without regard to that which has been employed previously. This specificity of action is also shown most markedly in the action of peptone and also in the extracts containing cholin when administered before or after the extracts of tissues. Our protocols (Tables 1 to 10, inclusive) show the effect produced by these substances on the blood-pressure of the dog.

TECHNIC

Extracts and Solutions.—All extracts were made from fresh tissue, minced, ground with sand and mixed with physiologic salt solution, 1 c.c. for each gram of tissue. After macerating for an hour or so, the solution was filtered through glass wool. Control extracts from normal dog tissue were made immediately after killing a dog, the brain, thyroid, spleen, pancreas and testes being removed and prepared as described.

It was found that a potent dose of thyroid, especially if the tissue was hyperplastic, was 0.5 c.c. of extract (0.5 gm. of tissue) per kilogram. Peptone control was made in 10 per cent. solution and administered in the same dosage, 0.5 c.c. per kilogram. Various commercial extracts of thyroid were used as controls and found to possess less marked effect on blood-pressure than fresh extracts.

To obtain serum, the patient was bled into a flask of about 180 c.c. capacity, and on the following day, after contraction of the clot had taken place, the serum was separated. The dose of serum producing marked effect in suitable cases was found to be from 2.5 to 4 c.c. per kilogram.

Operative Procedures.—Dogs anesthetized with ether after a preliminary dose of morphin were used for our series of experiments. For securing a direct blood-pressure tracing on the long paper kymograph the left carotid was used; when the vagus was stimulated the nerve on the right side was used. The extracts and serums were injected with a syringe of suitable size into the right femoral vein. Half saturated magnesium sulphate and also the usual sodium carbonate and sodium bicarbonate solutions were used to prevent clotting. In our first experiments a transmitting tambour was used in producing tracings; later a float and the direct method were employed.

The accompanying tables give a complete record of all the experiments performed. Though there are a great many negative results, we feel that they may be of interest to others and that they should be published in detail.

DISCUSSION OF TABLES

The first experiment described in Table 1 shows the great drop in blood-pressure produced by a single injection of extract of hyperplastic thyroid. Table 1, No. 2, demonstrates the presence of an unusually potent depressor, as is also shown by the effect of the same extract in Table 5, No. 6. The tolerance produced by the first injection toward subsequent injections is shown in Table 1, No. 3. In general, it may be stated that this tolerance is most manifest when the first injection produces a marked reaction. Table 1, No. 5, shows good tolerance to fresh extracts after the first injection and also the typical action on both first and second injections of decomposed extracts. Atropin inhibits the action of cholin; that this drug has no effect on the action of the depressor in fresh extracts of hyperplastic thyroids is shown in Table 1, No. 6.

The series of experiments given in Table 2 is small, but at least two of the experiments are of interest. The same phenomenon may be noted in both No. 2 and No. 3; that is, tolerance produced by a good drop on the first injection of extract of hyperplastic thyroid, and the lack of any effect when serum from a patient having exophthalmic goiter is injected. The second extract injected in Table 2, No. 2, probably had undergone some proteolytic change. No. 3 also shows the action of a peptone solution and extract of carcinoma, with tolerance to second injections of each substance.

Four experiments in Table 3, Nos. 4, 5, 6 and 7, show no effect when extracts of non-hyperplastic goiters were injected after primary injections of extracts of goiters

* Dog died at once. Injection into external jugular.

with hyperplasia. Iodothyrin was used twice in this series (Nos. 2 and 3) as a control substance, with no effect. No. 8 illustrates well the action of extract of brain. This is probably a cholin action; the comparison between this action and that of decomposed extracts is striking (see Table 1, No. 5). The tolerance toward the pressor substance on second injections of pituitary extract, shown in Table 3, No. 9, is characteristic of this extract.

The effects of injecting serum from patients with different degrees of intoxication has been made the subject of a separate study and is reported elsewhere.[10] The patients from whom serum was used (Table 4, No. 1, Table 5, Nos. 1 and 2, and Table 6, Nos. 2 and 4), were all acutely toxic from exophthalmic goiter. The rest were not at or near the height of their intoxication. The apparent tolerance for extracts of hyperplastic goiters, produced by first injecting serum from patients having exophthalmic goiter, is seen in Table 5, Nos. 1, 2 and 4. We should expect a greater drop in blood-pressure here, as the extracts were made from typical hyperplastic goiters. Table 4, No. 4, is also worthy of note as concerns the last substance used. This extract, eight days old, gave a remarkable rise in blood-pressure each time it was injected. It is evident from Table 5, No. 7, that eight hours is sufficient time in which to produce marked change in the character of an extract.

Table 6 requires but little comment. The great effect of injecting serum in No. 2 had no effect on the subsequent action of an extract of prostate. No. 7 also shows the marked depressor action of extracts of this tissue. Atropin has no effect on the action of peptone (No. 10), but does inhibit the action of a decomposed extract in the same experiment.

The six experiments in Table 7 show, on first injection, the presence of a depressor substance in non-hyperplastic goiters (adenomas) somewhat similar in action to that of extracts of goiters with hyperplasia. That there is at least great difference in dosage is brought out in No. 4, in which experiment there was a fall of 30 mm., when an extract of hyperplastic goiter was injected after tolerance was established to extracts of adenomas. The action of extract of sarcoma after extract of goiter (No. 5) should be noted and that of extract of carcinoma of the breast after cutting both vagi (No. 2).

Of Table 8 very little is to be said regarding the three experiments in which serum from patients with simple, non-hyperplastic goiter was injected first. The second experiment in this series shows the more marked effect of serum from patients having exophthalmic goiter, also an apparent tolerance produced thereby for extract of hyperplastic goiter. The cause of death in No. 3 is unexplained.

The experiments in Table 9 add little to our knowledge, but the marked action of the extracts of exophthalmic goiter is emphasized in comparison with the control substances in the first three experiments, and No. 4 is of interest because of the action of the serum after the large drop and tolerance from extract of sarcoma.

The last large group of experiments, given in Table 10, shows the action of various control substances. Nos.

[10] Blackford, J. M., and Sanford, A. H.: Med. Rec., 1913.

7, 8, 9 and 10 have been grouped together because extracts of thyroids from dogs were injected. The results were not constant, however. Peptone was the only substance used in No. 11. Tolerance was established to the first dose. When three times this amount was administered there was a large drop, with tolerance to another injection of the same quantity. The strange preliminary rise of the blood-pressure, followed by a fall, caused by extracts of spleen, occurred in only the three experiments, Nos. 15, 16 and 17.

While a study of the individual experiments shows many exceptions, our general findings are stated in the summary.

SUMMARY

1. Extracts of exophthalmic goiters cause a very marked fall in the blood-pressure of the dog, with

splanchnic dilatation and slowing of the pulse. The first injection produces tolerance toward subsequent injections. Atropin does not affect the action.

2. The serum of patients at the height of intoxication from acute exophthalmic goiter causes a marked fall in blood-pressure; tolerance is produced.

3. The only subtsances we have used that produce comparable drops in blood-pressure with tolerance are Witte's peptone (10 per cent. solution) and extracts of sarcoma and hypertrophied prostates.

4. Brain extracts and extracts of decomposing tissue containing cholin produce very different drops in that there is no tolerance produced, and atropin inhibits their action.

5. The tolerance produced to extracts of sarcoma and prostate or peptone solutions does not protect the ani-

mal from the typical action of the extracts of exophthalmic goiter.

6. The tolerance of the serum of exophthalmic goiter apparently protects the animal against the action of the extracts of exophthalmic goiter.

CONCLUSION

There is a powerful depressor substance in saline extracts of exophthalmic goiters, and apparently the same substance is present in the blood of individuals suffering acutely from this disease.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. WILSON, SMITH, SANFORD AND BLACKFORD

Dr. E. T. Bell, Minneapolis: I should like to ask Dr. Wilson to explain his grouping of the toxic cases.

Dr. A. W. Hewlett, Ann Arbor, Mich.: Was the fall in blood-pressure from exophthalmic serum prevented by a previous injection of exophthalmic extract?

Dr. A. H. Sanford, Rochester, Minn.: Apparently tolerance to the depressor substance in an extract of exophthalmic goiter would prevent the fall in blood-pressure from a potent serum of an exophthalmic goiter patient. I use the word "potent" because only in the acute stage of intoxication is a depressor substance obtained. We have used altogether about twenty-six serums and about forty-nine extracts. Some of these serums were from patients with simple goiter. These serums contained no potent depressor substance. We also used serums from normal persons and from the horse. We found no drops in normal serums.

Dr. A. W. Hewlett, Ann Arbor, Mich.: We have injected the serums from patients with high blood-pressure into dogs and rabbits and in these cases there was a striking fall in blood-pressure. We were under the impression that this fall might occur after injections of normal serums.

Dr. L. B. Wilson, Rochester, Minn.: The grouping into toxic non-exophthalmic and into toxic exophthalmic cases is purely clinical. It is found that the exophthalmic toxic cases invariably show hypertrophy and hyperplasia, while the non-exophthalmic cases do not show these symptoms.

Dr. A. H. Sanford, Rochester, Minn.: There was a fall in blood-pressure even after both vagi were cut. Furthermore, Gley and Cleret in their series stated that there is inhibition of vagus action after the injection of the serums and goiter extracts. We could not demonstrate this. By the use of the intestinal plethysmograph we were able to demonstrate that a marked splanchnic dilatation occurred coincident with this fall in blood-pressure. We injected these serums as we obtained them from patients without noting their histories. Sometimes we obtained marked fall in blood-pressure and at other times nothing at all. We did not know beforehand what our results would be. In reviewing the case histories it was found that the serums in which we had a marked fall in blood-pressure were from those patients who had acute intoxication from exophthalmic goiter and that those from which no effect was obtained were from the chronic cases. It appeared to us quite significant as to the amount of depressor substance present in the blood of these patients at that particular time.

Rural Sanitation.—In many states the large cities are the only points which have any real sanitary protection. Our rural population of 49,000,000 people, including the 30,000,000 who live on farms, with the exception of those fortunate rural dwellers in one or two exceptional states which regard the health of the country people as also important, receive very little state health protection and maintain no local protective system of their own against contaminated local milk, meat, shell-fish, fish or vegetables. Moreover, only a small number of these rural inhabitants are safeguarded, by competent inspection, against polluted water-supply or sewage-disposal methods dangerous to health and life.—*Carl L. Alsberg, Am. Jour. Pub. Health.*

FIELD-WORK IN TUBERCULOSIS *

MARY E. LAPHAM, M.D.
HIGHLANDS, N. C.

It is small comfort to a man dying of tuberculosis to be told that, if the disease had been discovered in time and properly treated, his life might have been saved. It is more than doubtful if the frequency of this failure to discover the disease in time is adequately appreciated outside a sanatorium. There we learn with appalling emphasis the lesson taught by experience that death in tuberculosis is not entirely due to an infection by tubercle bacilli, but equally, and possibly more than equally, due to failure to detect the beginnings of pathologic processes. The fault is not altogether in the inability or the neglect of physicians, because only too often the patient is all unconscious of the danger and does not seek help. It is to emphasize the importance of educating the people to a sense of this danger that this paper is written.

These cases of delayed diagnosis in which the patients do not seek a doctor until it is too late are due to lack of manifestations, so that the patient is not aroused in any way to the fact that there is any trouble in his lungs. He does not cough, has no fever, feels well, looks well and does his day's work with ease. We have at the Highlands Camp Sanatorium under our care patients who, up to the very time that they finally felt ill enough to call in a doctor, were feeling as well and working as well as they ever had. How shall we teach our people to realize that apparently good health is no guarantee against tuberculosis and that good working capacity is perfectly compatible with bad lungs? How can we make them appreciate the dangers of tuberculosis among apparently well people and the desirability of guarding against its spread and development by periodic examinations? How can we explain the long years of preparation and teach them that the victims discovered to-day have been years in the making, and that, therefore, the time to attack tuberculosis is not at the end, when it is perforce discovered, but during those long years of slow development when the crops were growing?

The recent work done in the South against the hookworm with such splendid results suggests the desirability of employing just such tactics against tuberculosis. In the South our people did not know why they could not work or that they had hookworms or that they could be cured. They had no hope of help and rarely sought it. By going out into the field and searching out these cases and teaching the people and the physicians on the spot an incredible amount of working capacity has been acquired for the South and this saving will steadily increase while the expenses of the campaign will lessen and cease. In the ordinary course of events how long would it have taken for this knowledge to filter down through to physicians and patients?

If another Rockefeller would establish a fund for field-work in tuberculosis so that we could plan the campaign along the same lines as that against the hookworm and put a tuberculosis expert in charge of each district, what should we hope to accomplish? First, we should want to educate the people so that they would understand the problems connected with the prevention of the disease; and, second, we should make a thorough canvass in order to learn how many cases of unsuspected latent tuberculosis were insidiously preparing to become manifest.

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

The district physicians will make a thorough search for suspicious cases and bring them for examination on the appointed day by the expert. This will teach the profession the most reliable and newest methods of examination and enable them to learn to detect the presence of a tuberculous process long before there are any manifestations. The expert will insist on the examination of apparently well children because he knows that it is precisely among these seemingly well children that concealed tuberculosis is found, and that if these cases are put under proper treatment many an adult will be saved. The expert will teach his physicians the necessity for distinguishing between an infection by tubercle bacilli and tuberculosis, because whereas over 90 per cent. of our children are infected by tubercle bacilli by the time they reach maturity, only a very small percentage manifest the disease and it is therefore evident that not all these infections develop into a tuberculous process. We can detect the unsuspected presence of tubercle bacilli by a tuberculin test, but this may be simply a biologic and not a pathologic reaction. The ability to react to tuberculin increases with each year of life from birth to maturity, so that we as constantly find an increase in the number of infections by tubercle bacilli, but this does not mean that the manifest cases of tuberculosis increase in the same proportion.

From birth to maturity there is an ever-increasing disproportion between the percentage of tuberculin reactions, the manifested cases of tuberculosis and the death-rate. We cannot tell by a tuberculin test whether or not a new-born babe has a tuberculosis infection because the ability to respond to tuberculin is still undeveloped.

With every year of life we find an increase in the number of children responding to tuberculin and we have argued from this increase a corresponding increase in the number of infections. This inference may be wrong in some cases because instead of a new infection we may have simply a newly developed ability to respond. Every day the study of the newly born and of the prematurely born is showing with ever-increasing frequency the presence of acid-fast bacilli or their prebacillary forms known as Much's granules in the blood and tissues when there was absolutely nothing to suggest their presence. The latency of the infections is so great that we are beginning to believe that they are as universal and as harmless as those by colon bacilli.

It is possible that the story of tuberculosis begins at birth and that the growing organism has to decide at the very start the question of its relations with this infection. If it is able to assert a phylogenetic ability to retain acid-fast infections in a state of harmless residence, as we all do colon bacilli, then tubercle bacilli are not dangerous to that individual. If there is a flaw in this mechanism, if the adaptation is not complete, the manifestation of this flaw will depend on an infinitude of factors. If the failure is conspicuous, the newly born will manifest it and die. One per cent. of all our children manifest this failure during the first year of life and die, not because they have been exposed, but because they have failed to adapt themselves. These failures inevitably die because they have never established the ability to live and the proportion between the number of manifest cases and the deaths is 100 per cent. The proportion of the death-rate to the total number of children is 1 per cent., and the percentage of infections is the same. Even in the second year of life discrepancy appears between the percentage of tuberculin reactions, the manifest cases and the death-rate, because no distinction is made between the tuberculin reactions and the manifest cases.

We argue from the increased number of reactions an increase in the number of infections and because the death-rate does not correspondingly increase it falls in proportion. If we should carefully distinguish between these tuberculin reactions and the evident manifest cases we might find that the death-rate was the same for these as in the first year of life and that the discrepancy was solely due to an increased ability to respond to tuberculin. That this is true is supported by the fact that acid-fast bacilli and Much's granules are found in infants that do not respond to tuberculin until later. With each year this discrepancy becomes greater until at maturity we find over 90 per cent. of tuberculin reactions and a death-rate of only 2 per cent. These figures will not reveal their true significance until a careful estimate is made of the distinction between manifest cases and biologic reactions. It may be that we shall find the actual death-rate higher at maturity than at any other period of childhood because of the ever-developing slowly manifested inability to live in safety with tubercle bacilli. It may be that the child that dies at 14 does not die because of a new infection but because the disparity between the danger from the infection and the ability to resist it increases. If this proves true, the tuberculosis work in the future must be directed toward detecting the children threatened with this failure and endeavoring to correct it. Prophylaxis will consist in preventing the development of this flaw and never allowing it to go on to the tuberculosis of adults.

To be able to distinguish between pathologic and biologic reactions our experts will need a well-equipped laboratory and Roentgen apparatus. This will mean great diagnostic skill and a great deal of work with consequent need of assistance. This will give our recent graduates a splendid opportunity to learn the most difficult task of distinguishing between a simple presence of tubercle bacilli and their assumption of pathogenic qualities. The keeping of these records and their comparison with the subsequent histories will teach us more concerning the relationship of these childhood infections with the tuberculosis of adults than we could possibly learn in any other way. We know that primary infection of the adult is impossible, but we do not know the history of these years between the primary infection and its final manifestation. By periodic examinations of our patients we can reveal these connections and study the effect of saving the child on the future death-rate from tuberculosis. This great effort cannot be forced on the people by the profession and they must therefore be taught to demand it, and to see that their future safety depends on it. The expense seems prohibitive, but we may come to realize that the money has to be spent anyway, and that it is only a question of when and how—whether we shall build and maintain sanatoriums for manifest cases and be utterly unequal to the problem of caring for them all, or whether preventoriums will not save years of wasted educational and living expenses lost at the very time the expense was to be justified.

The campaign of education will be greatly furthered by the stimulus to the comprehension of the people from the practical work carried on among them. Explanatory of these results, they will understand pathologic sections of lungs made during all stages of the disease, from the tissues swarming with the bacilli and yet not in the least injured, to the rotten lungs reeking with corruption.

Lectures illustrating the slow development of these processes in apparently well people and their compatibility with good health and working capacity will stimulate a desire for protection against this danger so subtle that it cannot possibly be appreciated. Above all else, the length of time should be emphasized, because there is a strong belief that an infection by tubercle bacilli resembles other infections, such as typhoid, and that recovery is, therefore, comparable to that from typhoid. If the people could be made to understand the nature of recovery in tuberculosis there would be fewer deaths from idiotic impatience. In our schools the teachers and pupils can be easily taught the whole story of tuberculosis as soon as the knowledge is sufficiently diffused to furnish us with teachers. How else can this be done as quickly as by field-work done just as it was against the hookworm?

We guard our schoolchildren from infection in every way we can, but there are two sources of infection that do not sufficiently attract our attention. One source is in the unsuspected carriers of tubercle bacilli that during a lifetime cough a little, or have "winter colds" or "chronic bronchitis," but whose general health and appearance do not suggest tuberculosis. One man complacently told me when he brought his wife that he had lost two wives from tuberculosis and probably he would lose this one, which he did. This man was the unsuspected carrier of tubercle bacilli. A few months ago the mother of one of my patients died at 68 and tubercle bacilli were found just shortly before her death, but not until after two of her children had died from tuberculosis. We distinguish between the danger from cases with tubercle bacilli in the sputum and those without. In many cases the prebacillary forms of Much's granules are present when the adult bacilli are not and their virulence is equally great, if not greater, so that the distinction between an open and a closed case must be changed to sputum containing no Much's granules and not capable of causing tuberculosis in a guinea-pig by inoculation.

Prophylaxis in the future must consist in preventing the development of a universal infection common to all mankind. which can in no way be avoided and only restrained. The direct transmission from case to case is entirely inadequate to account for this universal infection and we must seek some other explanation. We know that throughout the grasses and among trees and with the lower cold-blooded animals such as snakes, fish, turtles and lizards, and with the higher animals, such as birds, poultry, cats, dogs, sheep, pigs and cows, each class has its own peculiar kind of acid-fast bacilli capable of producing tubercles and manifesting their genetic relationship to each other by tuberculin reactions. That these tubercle-producing acid-fast bacilli are universally present throughout Nature and that they all belong to the same family is unquestioned, and that changes in type can be induced by changes in the host is indisputably proved.

Starting with these undoubted facts, it may be eventually proved that the universal infection of the human race by acid-fast bacilli is comparable with its universal infection by colon bacilli and that the danger essentially consists in the assumption of pathogenic qualities. As a rule the human race has acquired the ability to restrain this assumption, but occasionally in a very small percentage of cases this ability cannot be established and tuberculosis results. The detection of this change at the earliest possible moment and its conversion into safety is the fundamental basis of our future efforts against the spread of tuberculosis. Periodic examinations of our schoolchildren would do much to reduce the tuberculosis of adults.

Highlands Camp Sanatorium.

ABSTRACT OF DISCUSSION

Dr. Rosina Wistein, Chicago: I do not agree with Dr. Lapham that the education of the public must come from the laity, and not from the medical profession. The laity are ignorant of the dangers that are confronting them; and I believe that it is the duty of the medical profession to teach others, and only in proportion as we are interested can we hope to interest others. I find the greatest indifference and carelessness not on the part of the laymen, but on the part of the medical practitioner.

Severance Burrage, Ph.D., Indianapolis: I have met all kinds of people in this antituberculosis work, and I wish to corroborate what has been said in regard to the inactivity and careless attitude of physicians in general. In Indiana we are organizing the whole state in an antituberculosis campaign. We are organizing a local society in each county to carry on a campaign of education and disease prevention in that county. We find that the women are the best workers in most of these organizations, and that the physicians are really the hardest ones to induce to do active work. Some of them seem to feel that if they take an active part in a campaign for a local hospital — tuberculosis hospital — it will give the appearance of local advertisements or create certain jealousies among the physicians that will be undesirable, and will be looked on, possibly, as unethical or outside the pale of the physician's etiquette. For that reason we have found it difficult in many cases to enlist the active interest of physicians in the antituberculosis work. Some of the best workers are schoolteachers. They have a great deal of teaching to do, anyway; and just as schoolteachers are oftentimes enlisted in the Sunday-school work and in other kinds of teaching, they are also enlisted in this work. It does not seem right to me; I think that in a community in which facts in regard to disease—causes of disease and disease prevention—are concerned that the physicians should be the leaders in this educational campaign. They are the ones to whom the public should look for accurate information on these subjects; and yet, as I have stated,.we find in the majority of cases that active workers among the physicians are hard to find.

Dr. C. C. Browning, Los Angeles: I believe that the plan of fieldwork which the doctor has mapped out is worthy of more than passing notice. On account of my connection with the state tuberculosis commission of California, I have had occasion within the last two years to consider this subject somewhat carefully. We have adopted in our report a scheme founded on the campaign against the hookworm in the South. Our recommendation is the division of the state into sanitary districts, each of which is to be presided over by a dispensary physician, aided by a corps of nurses, for the express purpose of the detection of tuberculous patients. I believe that this plan promises the greatest amount of good in the future for the amount of money expended.

Dr. W. A. Evans, Chicago: There is, I think, a general consensus of opinion that tuberculosis in the cities is on the decline. Among the older cities—cities along the Atlantic seaboard—and the cities of continental Europe, the decline is about 50 per cent. in round figures. In our section of the country—in the Middle West—the decline is about 25 per cent. Our campaigns were not inaugurated so early as were the campaigns to the east of us, and probably they have not been so effectively conducted. It seems to me that the teaching of these experiences is quite conclusive that in communities that have undertaken this work thoroughly results follow, and that we are justified in concluding that tuberculosis will respond to efforts at its control. There are probably some states in which there is a decline in tuberculosis outside of the cities; but in the main, I think, the statement is true that there is—aside from the increasing amount of discovered tuberculosis—an actually increasing amount of tuberculosis in the rural districts.

The work for the control of tuberculosis in the rural districts is not so well developed as in the cities. I know of the plans that are being pursued in various cities in the vicinity of Chicago. It has seemed to me that the best of those plans was that in operation in Wisconsin. In Illinois the women's clubs are conducting a tuberculosis survey—a survey the results of which will be inaccurate, but which, nevertheless, will serve to concentrate the attention of the women on the tuberculosis problem in their respective communities. We are employing visiting nurses, under the auspices of the state tuberculosis society. A nurse investigates conditions in one county, and the idea is that when she leaves and moves over to another county there will be left behind in that county one or more local county nurses maintained by philanthropy. So far as I know, this idea has been better worked out in Wisconsin than in any other state in the Union, certainly better than in any other state in our part of the country.

Dr. Gertrude Felker, Dayton, Ohio: Four years ago the House of Delegates gave to the women physicians of the American Medical Association the task of forwarding the education of the people. This committee is now known as the Committee for Public Health Education Among Women. The effort has been to find some physician in every state who would be interested in education; and through that physician as state officer to find some one in each county who would talk public health education and have in each county society a public health education committee appointed. We have asked that a woman be put on that committee in counties in which creditable work is being done by women physicians. After four years' work almost five hundred counties have appointed committees.

Dr. Mary E. Lapham, Highland, N. C.: The purpose of my paper was to urge the appointing of an expert from the medical profession to teach the people the earliest suggestions of tuberculosis. The education of the people shoud come from the profession. The earliest recognition of tuberculosis must come from the people in order that the profession may have the earliest opportunity to confirm it. It is because the people do not understand the situation that the general practitioner does not have the opportunity to make a sufficiently early diagnosis.

THE HISTOPATHOLOGIC LOAN COLLECTION AND RELIEVING THE CURRICULUM *

H. S. STEENSLAND, M.D.
AND
H. G. WEISKOTTEN, M.D.
SYRACUSE, N. Y.

It was pointed out by Bardeen[1] that it is essential to have *good* histologic preparations if the student of normal histology is to see the details of structure as they exist in the tissues. Otherwise he is likely to make mistakes and to draw wrong conclusions from what he sees, and perhaps eventually to fabricate from grosser features of a histologic preparation the finer details that it does not present. This is just as true in the case of pathologic histology. A common method of handling routine teaching material is to give the student sections which he is expected to stain and mount for himself. Another practice is to distribute stained sections for the student to mount. Frequently it results that the preparations are not satisfactory and that much of the time and energy of the student is wasted in puzzling over them. For this reason it would appear to be wise to make extensive use of loan preparations.

The amount of time that can be given each year by members of the teaching staff to the preparation of histologic teaching material is limited. If this time is given to the making of a limited number of permanent loan preparations of high quality covering a limited field, there will accumulate eventually a loan collection of high grade covering a large field. Then there will be histopathologic loan collections comparable to the Minot embryologic collection at Harvard and the Mall embryologic collection at Johns Hopkins. Also the student will have for study carefully selected material, well fixed, cut into thin sections, and carefully stained and mounted. The time that the student formerly gave to the routine of staining and mounting sections he can give to actual study of the preparations.

It may be objected that the student should have the technical experience involved in staining and mounting; but with the gain in time he can be given a short but more varied training in technic in place of the oft-repeated routine. The ownership by the student of a collection of sections is a doubtful advantage as compared with the length of time that he spends in staining and mounting. The sections probably are rarely referred to after the course is completed. The mere collecting of the specimens is apt to be uppermost in the student's mind in place of the more important careful study of the material. It is not necessary to have one preparation of each kind for each student. One preparation for each pair or larger group of students is sufficient. The selection of material for permanent preparations for teaching purposes and the preparation of this material up to the point of orienting the blocks of tissue should have expended on it the greatest skill that the staff affords.

A modern course in pathology requires the use of a larger amount of experimental histologic material than was used ten or fifteen years ago. It is necessary to use to a larger extent tissues affected by means of known injurious agents under accurately known conditions. The amount of time required for the preparation of such material is very large, and the amount of material yielded by each experiment is frequently small. It is therefore obviously impossible to duplicate such material as frequently as would be required for giving each student a specimen as his personal property.

At Syracuse a loan collection as above set forth was begun by one of us (Steensland) ten years ago. A large gift from Dr. Mallory of imbedded specimens selected from his Harvard teaching material formed the nucleus of the collection and constituted a model and ideal of quality toward which to strive. As a result of the use of special care in the technic to prevent fading of the stains the oldest material is to-day apparently as good as when first prepared. Additions can be made to the collection as advances in the knowledge of diseased tissues require, and antiquated material can be replaced by new material. Each year special selection from the collection may be made for use by the students according to the trend in special directions which is given to the course in that particular year.

Pearce[2] and Gay[3] have pointed out the great advantage of correlating the work in experimental pathology and pathologic physiology with the work in pathologic histology. With a given number of scheduled hours the possibility of gain in time resulting from the use of a loan collection has an important bearing here. This gain in time for the student and the teaching staff will permit of the introduction of more work in experimental pathology and pathologic physiology into the usual course in pathology. The amount of such work that can be done by students in any particular department will depend on the size of the staff, the equipment, the possibilities of cooperation with other departments, the proximity of hospitals, the nature of the departmental divisions in the school involved, and other considerations. Any relief from routine, such as the use of the loan collection will afford, as pointed out above, will allow the members of the staff to give more of their best thought to improving and extending the teaching. The use of the loan collection offers a method of relieving the curriculum. It aids in providing time for the experimental and physiologic aspects of pathology, which are essential to the proper training of men who are to devote their lives to so large an extent to the study of the physiology of disease.

LONGITUDINAL FRACTURES OF THE TIBIA BY TORSION

WITH REPORT OF A CASE

R. W. McNEALY, M.D.
Instructor in Senior Surgery, University of Illinois, College of Medicine
CHICAGO

Longitudinal fractures of the tibia usually result from indirect violence as in jumping or falling from a height, and in these cases a T- or Y-shaped fracture is usually produced in which one or both tuberosities are separated from the shaft and the joint cavity involved. In fractures of this type due to direct violence it is more common to have a comminuted fracture, often compound.

Fractures from torsion or twisting occur most frequently in the humerus or femur or in the shaft of the tibia near the middle. In the humerus they are usually spiral and result from extreme passive torsion as in wrestling or in throwing a ball. We see this variety again in the fracture, or rather the epiphyseal separation, seen in small children as the result of being supported by the hand after stumbling and falling with body rotation. In the femur and tibia they usually result from a fixation of the foot with rotation of the body, which was the case in my patient.

REPORT OF CASE

History.—Mr. B., aged 42, an extremely muscular man weighing 238 pounds, has always been in perfect health and for the past sixteen years has been engaged as fireman in the Chicago City Fire Department. He is an unusually active man for his weight. On April 24, 1913, he attempted to board a moving street-car as it was rounding a corner. Owing to the fact that another passenger wishing to alight was standing on the platform, he was able only to get his right foot on the step and to catch the rear handle of the entrance. His foot being firmly anchored on the rubber-covered step, which prevented its slipping, he was able to stand aright, but the momentum of the car swinging out around the corner caused him to twist suddenly and his body to swing around to the rear of the car while he still maintained his grasp on the handle of the car and his foot-space on the step. He did not lose his footing or fall at any time, but felt something crack in his leg and experienced severe pain when he regained his balance and walked into the car. The pain increased rapidly and he had to be carried from the car.

Examination.—The patient is unable to bear his weight on the leg but does not believe it broken, as he was able at first to walk. The signs of local trauma in the way of discolorations or ecchymoses are lacking. There is some swelling about the knee-joint. Crepitus can be elicited easily on passive motion. There is no marked deformity, the leg being in perfect alignment. Increased lateral mobility is present. Measurements as to length are normal. Tuberosities of the tibia are quite markedly increased in width. Roentgenoscopy shows a rather unique fracture of the upper portion of the tibia. There are apparently three distinct lines of longitudinal cleavage extending from the interarticular space of the superior articular surface in a right-twisting spiral to well past the middle of the tibia. A V-shaped fragment is left between the articular surfaces, probably the result of the firm attachment of the crucial ligaments to the spines.

Treatment.—Temporary lateral splints and ice-bags were applied to the knee until the following day, when an attempt was made to mold the knee by lateral pressure on the tuberosities of the tibia. A plaster-of-Paris cast was applied extending from the groin down to the toes. The cast was opened anteriorly and posteriorly by means of a Gigli saw as soon as dry, adhesive plaster being used as a hinge posteriorly so that the cast could be removed and passive motion and massage instituted. Passive motion and massage were begun gently on the eighth day and continued with increasing activity. The patient was able to go back to work in eleven weeks.

It is my purpose in reporting this case not alone to call attention to unusual factors in the mechanism and pathology, but also to emphasize the necessity of, and excellent results accruing from, early passive motion in fractures involving joints. The patient reported in this case is able to walk with absolutely no limp and could touch heel to buttock on the injured side after eleven weeks.

INJECTION OF QUININ AND UREA HYDROCHLORID IN HYPERTHYROIDISM

PRELIMINARY REPORT

LEIGH F. WATSON, M.D.
OKLAHOMA CITY, OKLA.

The following cases are reported to show the immediate results on the symptoms after injecting quinin and urea hydrochlorid. The patients have all been on medical treatment for from one to two years without improvement. In Case 1 the injection was used in conjunction with ligation of both superior thyroid arteries; in Cases 2 and 3 the injection was the only treatment employed. Improvement seems to be equally prompt without the ligation; whether or not the results will be as lasting as after ligation remains to be proved.

If there is any pain following the injection of quinin and urea hydrochlorid it is very slight, and is limited to the site of injection. A moderate degree of swelling is noted after injecting, which disappears within a week.

An all-glass syringe with a slip-joint platinum needle 2 inches in length is used for the injection.

Case 1.—Mrs. S. K., married, schoolteacher, has had family trouble for the past few years. Goiter was first noticed three years ago while the patient was spending her vacation in Colorado at a high altitude. The enlargement and symptoms of hyperthyroidism have gradually increased in spite of medical treatment and rest. The patient is very nervous. Insomnia is marked. There is tremor of both hands. The pulse ranges from 130 to 160. There is considerable enlargement of the right lobe, about 3 inches in length. The left lobe and the isthmus are slightly hypertrophied.

Both superior thyroid arteries were ligated and 90 minims of a 1 per cent. quinin and urea hydrochlorid solution injected into the body of the right lobe, 60 minims into the left lobe, and the same quantity into the isthmus. The pulse was 160 at the end of the operation, in spite of nerve-block of the neck. The pulse was 150 the next morning, and 130 that evening, 112 the second morning after operation and 104 that evening. The insomnia, nervousness and tremor disappeared within forty-eight hours. The following week the pulse averaged 100, gradually becoming slower until it reached 80, at which point it now remains.

Case 2.—Miss H. S., aged 24, single, whose mother has had goiter for years, without severe symptoms of hyperthyroidism, and whose sister died of hyperthyroidism one month before, complains of nervousness, tachycardia, insomnia and a severe diarrhea of two years. The patient is losing weight. There has been amenorrhea for sixteen months. Tremor is most marked on the left side. The patient noticed goiter on the left side about two years ago, increasing in size until it now measures about 3½ inches in length. The right lobe is 3 inches long and the isthmus somewhat enlarged.

The skin at the site of the injection was infiltrated with a few drops of local anesthetic solution. Through one skin puncture over the center of the left lobe the needle was inserted and 25 minims of a 4 per cent. quinin and urea hydrochlorid solution injected at four different points into the body of the left gland. The procedure was repeated for the right lobe and the same amount injected; 30 minims were then injected into the isthmus.

The diarrhea stopped within twenty-four hours. The pulse was 90 after the injection and the general condition was improved. The patient is gaining in weight.

Case 3.—Mrs. W. D., aged 33, married, housewife; began teaching school at 16; in a few months she noticed increasing nervousness and insomnia with slight enlargement of the right lobe. Tachycardia was first noticed while the patient was teaching and attending summer school in 1897-1898, becoming steadily worse for the past two years under medical treatment and rest. The pulse varied from 120 to 160. The patient had diarrhea ten years ago, when her only child was 1 month old; this continued for two years; there has been none during the past year. There has been tremor of both hands for eight years. There has been no nausea. The appetite has always been good. There is slight exopthalmos. The average weight is 130; it was 105 at the time of the first injection: after the injection, the patient gained 10 pounds within two weeks. She complains of constant pain over both ovaries, most marked on the left side; menstruation with dysmenorrhea occurs every two or three weeks.

When the first injection was given the right lobe was about the size of a hen's egg, and the left about half as large, with a moderate hypertrophy of the isthmus. Forty minims of a 2 per cent. quinin and urea hydrochlorid solution were injected into each lobe and the isthmus. Improvement was prompt. On the day following the injection the pulse dropped to 90; for the next two weeks while the patient remained in bed the pulse was from 70 to 80, becoming slightly accelerated when she left her bed and resumed her housework. At the time of the first injection the condition of the patient was such as to preclude any form of abdominal operative procedure without jeopardizing her life. One month later she was operated on under general anesthesia with a thorough nerve-block of the operative field, left salpingo-oophorectomy, right oophorotomy and appendicectomy being performed. The cervical canal was flexed and markedly stenosed; dilatation and curettage were done. Throughout the operation the pulse was below 90. The patient was awake and talking while the abdominal wound was being closed. The pulse was 80 during the following week. After-pain in the wound was prevented by the use of quinin and urea hydrochlorid nerve-block.

At the second injection, ten days after the operation, examination showed a small, firm, circumscribed right lobe. The left lobe and the isthmus were also reduced in size. Thirty minims of a 4 per cent. quinin and urea hydrochlorid solution were injected into each lobe and the isthmus. Next day the pulse was 80, and normal on the second day, when the patient left the hospital.

Suggestion.—Suggestion enters the understanding by the back stairs, while logical persuasion knocks at the front door.—Bechterew.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

SODIUM ACID PHOSPHATE.—Sodii Phosphas Acidi.—Sodium Dihydrogen Phosphate.—Sodium Biphosphate.—Monosodium Orthophosphate.—Primary Sodium Phosphate.—Sodium acid phosphate, $NaH_2PO_4.H_2O$, is the monosodium dihydrogen salt of orthophosphoric acid, H_3PO_4, containing not less than 82 per cent. of anhydrous sodium acid phosphate.

Actions and Uses.—Sodium acid phosphate undergoes no change in the stomach. In the intestine it is converted into disodium hydrogen phosphate (secondary or neutral sodium phosphate). In large doses it produces laxative effects similar to those produced by the official disodium hydrogen phosphate (sodium phosphate U. S. P.). The neutralization of the acid phosphate is accomplished by alkali drawn from the blood. This tends to reduce the alkalinity of the system, which reduction is prevented by the excretion of acid in the urine. Sodium acid phosphate can thus be used to render the urine acid, or increase its acidity. It is used for this purpose to assist the action of hexamethylenamine which is effective only in acid urine. For this purpose sodium acid phosphate should be given long enough before the hexamethylenamine so that it may have left the stomach before the latter remedy enters it.

Dosage.—From 1 to 1.5 Gm. (15 to 20 grains) repeated frequently until the urine becomes acid. It may be administered in sweetened water like lemonade. It should not be prescribed in solution with hexamethylenamine.

Non-Proprietary Preparations:

Sodium Acid Phosphate, M. C. W.—Manufactured by Mallinckrodt Chemical Works, St. Louis, Mo.

Sodium Phosphate, Monobasic, P. W. R.—Manufactured by Powers-Weightman-Rosengarten Co., Philadelphia, Pa.

Sodium acid phosphate occurs as large, colorless, transparent crystals or a white, granular, crystalline powder; odorless and having a cooling, saline and somewhat acid taste; slightly deliquescent.

Sodium acid phosphate is very soluble in water; insoluble in alcohol, ether or chloroform.

At 100° C. (212° F.) sodium acid phosphate loses its water of hydration (13.04 per cent.); at 210° C. (410° F.) it is converted into disodium dihydrogen pyrophosphate ($Na_2H_2P_2O_7$). At still higher temperatures it is changed into a mixture of sodium metaphosphate ($NaPO_3$) and sodium trimetaphosphate ($Na_3P_3O_9$).

An aqueous solution of sodium acid phosphate (1 in 20) is acid to litmus.

An aqueous solution of sodium acid phosphate (1 in 20) yields a white, crystalline precipitate with an excess of magnesia mixture solution.

With silver nitrate solution an aqueous solution of sodium acid phosphate (1 in 20) yields a yellow precipitate which is soluble in ammonia water and in nitric acid.

If warmed with ammonium molybdate solution an aqueous solution of sodium acid phosphate (1 in 20) yields a yellow precipitate which is soluble in ammonia water.

If 1 Gm. of sodium acid phosphate be dissolved in 20 Cc. of water and the solution neutralized by ammonia water, not more than a slight turbidity should appear (limit of *calcium*, *aluminum*, etc.).

If 1 Gm. of sodium acid phosphate be dissolved in 100 Cc. of 1 per cent. hydrochloric acid, 10 Cc. of the solution should not respond to the U. S. P. time limit test *for heavy metals.*

If 0.1 Gm. of sodium acid phosphate be dissolved in 10 Cc. of 10 per cent. sulphuric acid, the solution should not respond to the modified Gutzeit's test for arsenic proposed for the U. S. P. IX.

If 0.1 Gm. of sodium acid phosphate be dissolved in 10 Cc. of 1 per cent. nitric acid and 1 Cc. of silver nitrate solution added, not more than a distinct opalescence should appear within one minute (limit of *chloride*).

If from 1 to 2 Gm. of sodium acid phosphate be dissolved in 50 Cc. of 1 per cent. hydrochloric acid and the sulphate determined in the usual way, the weight of barium sulphate found should correspond to not more than 1 per cent. of hydrated sodium sulphate ($Na_2SO_4.10H_2O$).

If from 1 to 2 Gm. of sodium acid phosphate be dried for 1 hour at 60° C. (140° F.) and the temperature be then raised to 100° C. (212° F.) and maintained there until the salt ceases to lose weight it should not lose more than 15 per cent. of the weight taken (absence of an undue amount of *water*).

If from 1 to 2 Gm. of sodium acid phosphate be weighed, dissolved in 10 Cc. of water, 10 Cc. of a cold, saturated solution of sodium chloride added, and the solution titrated with normal potassium hydroxide, using phenolphthalein as indicator, the amount of alkali consumed should correspond to not less than 82 per cent. of anhydrous sodium acid phosphate. 1 Cc. of N/1 KOH = 0.11917 Gm. of NaH_2PO_4.

If from 0.1 to 0.2 Gm. of sodium acid phosphate be weighed, dissolved in 10 Cc. of water, the solution neutralized with normal potassium hydroxide (free from chloride) using phenolphthalein as indicator, 50 Cc. of tenth-normal silver nitrate added, sufficient zinc oxide (free from chloride) added with stirring to render the mixture neutral to litmus paper, the mixture diluted to 100 Cc. with water, the mixture filtered through a dry filter, and the residual silver nitrate in 50 Cc. of the filtrate determined by titration with tenth-normal potassium sulphocyanate in the usual way, the silver nitrate consumed should correspond to at least 82 per cent. of anhydrous sodium acid phosphate. 1 Cc. of $N/10\ AgNO_3 = 0.003972$ Gm. NaH_2PO_4.

TETANUS ANTITOXIN.—(See N. N. R., 1913, p. 218.)

Slee Laboratories, Swiftwater, Pa. (The Abbott Alkaloidal Co., Chicago.)

Slee's Refined and Concentrated Tetanus Antitoxin (Globulin Solution).—Marketed in syringes containing from 1,500 to 5,000 units each.

NORMAL HORSE-SERUM.—(See N. N. R., 1913, p. 236.)

Slee Laboratories, Swiftwater, Pa. (The Abbott Alkaloidal Co., Chicago.)

Slee's Normal Horse Serum.—Marketed in vials containing 10 and 20 Cc.

AMPOULES EMETINE HYDROCHLORIDE, P. D. & Co.—This article has been accepted for inclusion with New and Nonofficial Remedies.

Each ampoule contains emetine hydrochloride 20 mg. (⅓ grain). Prepared by Parke, Davis & Co., Detroit, Mich.

Therapeutics

CONSERVATION OF ENERGY

Crile's work in the investigation of shock[1] and his theory of the power to withstand and the development of energy which he terms the "kinetic system" should be understood by every practitioner of medicine. He believes that the brain, the thyroid, the adrenals and the muscles of the body coordinate to develop what may be termed the power, the forcefulness, the power to withstand, or the reserve strength, of the system. If any one set of these organs is overworked, the body loses strength and symptoms of shock are liable to occur when any traumatic, emotional, toxic or drug cause for it exists.

The danger of "brain-fag" has long been understood. Though the brain can stand more hours of work than the muscles of the body, still when it is overworked, serious nervous disturbances may develop, or when some injury, operation or infection occurs the patient is likely to suffer shock, and the prognosis is not good, as the power to survive, or the ability to endure, the disturbance is greatly diminished. It is also being recognized that a brain is more readily overworked if the work is disagreeable or is beyond the mental capacity, or if too much or increased responsibility is placed on an individual during or just beyond the middle period of life. A middle-aged man whose brain is uneducated, if set at machine work, will probably suffer injuries from incoordination of muscle movements, or if compelled to do too much desk work, will make many mistakes. If an educated brain is suddenly overworked, the possessor is likely to have nervous breakdowns and perhaps become hysterical or neurasthenic, as such persons are overworking their thyroids and many times also their adrenals.

Shock, more or less acute, or muscle debility, more or less prolonged, from severe or repeated muscle tire, is recognized by all athletic instructors. As frequently seen by physicians, it is represented by variations of circulatory debility, with or without some cardiac dilatation, generally with lowered blood-pressure, due many times to nothing but muscular overexertion. If such patients suffer from traumatism or from acute infection, the tendency to shock is greatly increased.

Hyperactivity of nervous energy, strenuosity, so constantly seen to-day, among our best citizens, causes a varying degree of continuous hypertension, which probably means overstimulated adrenals and may result either from too much mental energy, from too much physical speed in daily life, or from a combination of the two, which we recognize when we state that a certain man is a "hustler," or is "making his mark in the world." The future of such a person is one of hypertension and long later cardiovascular-renal breakdown. This hypertension may be termed "controlled" and is probably governed by adrenal stimulation. While such a person—generally a man—is younger, and while his machinery runs smoothly, he is in perfect health and is doing his part of the world's work, but physicians recognize that if he suffers from any one of Crile's enumerated causes of shock, he is likely "to go to pieces." Such individuals often die unexpectedly from pneumonia or from the shock from injuries or surgical operations, or they break down during the active period of life from sudden loss of blood-pressure due to circulatory tire, or from cerebral disturbance due to brain-tire. These persons are using up their reserve energy and have none left for emergencies.

Another cause of the breaking of the kinetic chain is that disturbance of the thyroid which may be termed "uncontrolled hypertension" and which occurs mostly in women. This is a condition caused by social excitement and late hours, with the irritations of confusion, bright lights, late dinners, alcohol and coffee. Even if sleep is prolonged into the morning hours, energy is not thus conserved, but is constantly and progressively lost, for the recuperative hours are insufficient when compared with the hours of energy. Not only oversexual excitement, but unsatisfied sexual excitement is another disturbance of the thyroid part of this kinetic chain. One has but to note the abnormal, unphysiologic and immoral dance termed the "tango" to realize what is happening to the young people, especially to the hysterical, neurotic and socially or physically tired girl. Whether or not voluptuousness is aroused by these dances, the wear and tear on the central nervous system is enormous, probably to the disturbance not only of the thyroid but of the three other parts of the kinetic system. The results must be nervous exhaustion, exacerbation of any neurotic tendency, and in girls the development of more or less hysterical phenomena.

The effect of sorrow, grief or mental shock on the thyroid is well understood, and those who have been subjected to such depressing influences do not rally well when traumatic, surgical or infective emergencies occur.

---

[1] Crile, George W.: Shock, The Journal A. M. A., Dec. 6, 1913, p. 2027.

Consequently, the prognosis of recovery from illness in such patients is less favorable.

Some practical therapeutic conclusions to draw from the foregoing are that, except in an emergency, a patient who is to undergo operation should rest for several days, as the liability to shock will be diminished. Also, it is a serious mistake to starve a patient too long or to purge too severely before an operation. Such treatment tends to interfere with normal tone, probably because the adrenals may be disturbed. Also, it is good preparatory treatment to give a patient considerable amounts of carbohydrate foods for several days before operation, as when vomiting or stomach irritability occurs after operation, such foods cannot be administered for many hours, and sometimes for several days, and there is danger of acidosis from such carbohydrate starvation.

To aid in the conservation of the kinetic system during illness sleep is absolutely necessary. If this cannot be obtained by ordinary methods of fresh air, sponging the body with hot or tepid water according to the temperature of the patient, the proper care of the bowels and the proper kind of food, hypnotics are necessary. The temperature of the patient will always be lowered if good sleep occurs, as there is more muscle-rest as well as an absence of stimulation of all parts of the organism from a wakeful brain. Quinin, salicylic acid, caffein, atropin, or any other cerebral stimulant should not be given in the afternoon or evening to a patient who needs sleep. On the other hand, a sluggish, indolent brain that does not send its normal stimulation to the different parts of the body, perhaps not even to the adrenals, should be awakened in the morning with a cup of coffee.

The depressant action of prolonged insomnia in persons who are otherwise well and the consequent lowering of the power to withstand or the forcefulness of the kinetic system in possible emergencies should be recognized. Chronic insomnia, even if the patient obtains a few hours of sleep, is very serious and should be combated by every sensible method.

Nothing causes sleeplessness, especially in the sick, more than skin irritation, an uncomfortable bed, lack of smoothness of the undercovering of the bed, or an overheated or overchilled room. All of these irritants should be corrected.

Intestinal indigestion should, if possible, be prevented, as any absorption of proteins that have not disintegrated to the final product for proper absorption may be digested outside of the intestine, that is, absorbed before they have reached the molecular construction that is non-irritant. Such substances in the blood will cause one of two things: increase of the fever with anaphylactic symptoms, or depression, especially of the adrenals. Overdistention of the intestines with gas, which causes more or less intestinal paralysis, will also probably inhibit the adrenals. At any rate, such a condition seriously interferes with splanchnic circulation, and if the blood-vessels are not properly toned by sufficient adrenal vasopressor substance they widely dilate, and the patient is in a condition of shock.

In spite of the most discriminating care of the food received by the patient, there may be gastro-intestinal indigestion and absorption of depressing products. Also the germ of infection may produce depressant substances and the end-products of ordinary metabolism may be more or less retained in the system. Therefore our aim should be to promote elimination by all the emunctories, the bowels, kidneys and skin. The greater such elimination, the less likelihood of depression of the kinetic system; but the method selected for increasing elimination must depend on the condition of the patient. A patient who is severely prostrated should certainly not be profusely sweated. A patient whose circulation is greatly depressed, that is, a rapid, weak heart with a very low blood-pressure, should not be further debilitated by profuse bowel movements. Patients whose kidneys are irritated and more or less insufficient, especially if there is edema, should not receive large amounts of water in the hope of increasing the amount of urine; good judgment as to the amount of fluid advisable should be used with each patient. Ordinarily, during illness, goodly amounts of water should be drunk. The bowels should be moved daily, perhaps more than once a day. The skin, if possible, should be kept moist with spongings when indicated. The patient whose skin is dry and hot should not be sponged with alcohol as this tends to inhibit the normal secretions of the skin. A dash of alcohol in a large amount of water for sponging is simply absurd and should be discouraged; it means nothing but an odor. If there is profuse perspiration, however, and especially if there is prostration, pure alcohol sponging should be given, as it will tend to dry up the unnecessary hypersecretion.

Another mistake is to apply the ice-cap to every patient with high fever. If there is headache or symptoms of meningitis the ice-cap is of value; but high fever alone does not indicate that an ice-cap is needed. It has not been shown that such treatment ever reduced the temperature. It may, however, seriously depress the cerebral centers, perhaps disturb the nutrition of the hair and thus cause its profuse loss after the fever has subsided.

In the conservation of energy in patients who must be ill for some weeks, the necessary elements of nutrition should not be forgotten, namely, iron, given in substance, if the patient cannot receive meat or meat-juices; sodium chlorid; some of the fruit salts as represented by oranges; starch and perhaps sugar; some protein (and raw egg albumin may not offer good protein for absorption); lime, either as represented by milk or given as one of the calcium salts, and a sufficient amount of water.

To summarize, thorough physiologic therapy is always to be given to a patient.

Spanish Medical Periodicals Menaced.—Dr. De Diego deplores the way in which commercialism has invaded the drug business and medical publications of Spain. He warns against the present tendency as indicating a danger that the drug business and the medical periodicals may be monopolized by non-professional persons. Medicine for physicians and pharmacy for pharmacists, he thinks, should be the slogan. He says that of the sixty-odd legitimate medical periodicals published in Spain and Portugal less than six show a profit. The others barely pay expenses, and if the commercial house-organs continue their efforts to drive the legitimate medical periodicals from the field, the latter will have to suspend publication. He asserts that the fate of the medical press lies with the members of the profession, who should protect the legitimate publications with enthusiasm and energy, as the true medical press is of vital importance to the medical profession. His article is quoted *in full in the Siglo Medico*, Nov. 1, 1913.

PATHOGENICITY AND VIRULENCE OF BACTERIA

It is easy to understand how bacteria whose metabolism produces demonstrable toxic substances give rise to toxic symptoms in the organism which acts as host. To this class belong such bacteria as the diphtheria and tetanus bacilli. The pathogenicity of organisms which generate no such toxic substance or exotoxin is not so easily explained. Thiele and Embleton[1] have recently published experiments which suggest that the capacity of an organism to produce disease depends on the amount of toxic protein-cleavage products which *may be formed by the action of antibodies on the bacterial protoplasm.*

These authors divide the bacteria with which we are concerned into three groups:

In Group 1 they place the organisms against which the body produces very little antibody, as a result of which the bodies of these bacteria are very slowly broken down into simpler products, and hence these organisms are practically non-pathogenic.

In Group 2 are placed the organisms against which the body produces antibodies in moderate quantities. The bacteria are acted on by the antibodies or ferments, and are split into simpler compounds. This process is so gradual that the protein-cleavage products, not being immediately broken down beyond the toxic stage, accumulate in the system, and produce toxic symptoms. This group contains most of the pathogenic organisms.

Group 3 consists of those bacteria against which the antibody activity is very high. If these organisms succeed in growing within the body the protein substances are so rapidly broken down that they are soon split beyond the toxic stage, no toxic products accumulate and no symptoms are produced. These organisms are ordinarily non-pathogenic.

Thiele and Embleton made experiments in which they caused non-pathogenic organisms belonging to Group 1 to become pathogenic by raising the antibody activity against them. This was accomplished by giving a very large injection of killed organisms to guinea-pigs, and after a period of from five to fifteen days inoculating the guinea-pigs with a small quantity of the living bacteria. Animals so treated died in two or three days of intoxication. Control animals similarly inoculated but without the previous injection of killed organisms gave no toxic symptoms. These results indicate that bacteria non-pathogenic to certain animals became pathogenic when the antibody activity against them was increased. In these cases the presence of toxic substances in the blood was shown by injecting it into the veins of normal animals. Immediate death with the characteristic symptoms and post-mortem findings of anaphylaxis resulted.

Experiments were also made on organisms of the group regarded as non-pathogenic because the antibody activity against them is high. The injection of a quantity of hypertonic saline solution decreases antibody formation, and advantage was taken of this fact by injecting the organisms to be tested with such a *saline solution within the peritoneal cavity. Death from* toxemia resulted in every case. These results are interpreted to show *that the pathogenicity of bacteria depends* on the activity of the antibodies or ferments in the system of the host. If such activity is either very slight or very high the organism is non-pathogenic. By the increasing or decreasing of the antibody activity in the respective cases these bacteria may be made pathogenic.

Thiele and Embleton note that many non-virulent organisms on being made virulent develop a capsule. This phenomenon is apparently part of the process by which the bacterium modifies its characteristics to adapt itself to its environment. The antibody activity of the host represents an unfavorable condition, to which the bacterium must either adapt itself or perish. Becoming adapted to the hostile environment spells virulence, and the capsule formation which so frequently accompanies it is explained as follows: When a ferment comes in contact with an albuminous substance which it can attack it will gradually penetrate it; if this substance is a living bacterium it is destroyed. If, however, the bacterium develops the faculty of surrounding itself with a zone of such material and of renewing it by fresh extrusion from its own cytoplasm as rapidly as it is dissolved by ferment activity, the bacterium lives on unaffected. Virulence is then frequently an induced process, associated with the production of a capsule from which the toxic protein-cleavage products can be liberated by ferments, and which furnishes at the same time a barrier against phagocytosis.

The entire work impresses on us afresh the fact that the mechanism of pathogenicity and virulence is closely connected with changed activity or allergy on the part of the host, and that by a better understanding of the one we may attain a broader comprehension of the other.

THE VARIATIONS IN THE CONTENT OF SUGAR IN THE BLOOD

Alimentary glycosuria, as exhibited in the renal excretion of sugar when undue amounts of carbohydrates are ingested by persons who fail to manifest this symptom under ordinary conditions of diet, has long been recognized and investigated. The prominence which the clinical estimation of the sugar-content of the blood has assumed in recent months, and the diagnostic importance which has been attached to the variations in this blood-constant as a possible index of incipient metabolic disorder, have seemed to call for a careful determination of the precise effect which the ingestion of carbohydrate may exert in altering the quantum of blood-sugar under well controlled conditions in otherwise healthy persons. The determination of normal values and physiologic deviations from them is always essential as the rational beginning in the establishment of a new scheme of diagnostic procedure. Such an undertaking has lately been carried out in the medical clinic of the University of Copenhagen by Dr. Jacobsen.[1] Estimations were made after comparatively brief successive intervals in the same persons who had taken various substances in suitable quantities three or four hours after breakfast. It is well known that healthy persons frequently exhibit glycosuria after the ingestion of from 150 to 200 gm. of dextrose under similar conditions — and this is usually taken as an index of alimentary glycosuria. In contrast with some earlier studies the Danish investigator has observed an unmistakable hyperglycemia in every instance after ingestion of 100 gm. of dextrose; in some instances glycosuria likewise appeared simultaneously. In view of this fact, Jacobsen points out that a mild transient glycosuria under such circumstances is no longer to be looked on as a diabetic symptom.

Comparable quantities of starch administered in the form of bread likewise led to hyperglycemia. The increase in the percentage of sugar was quite as pronounced, in some cases, as that which occurred after the introduction of glucose; but the onset of the hyperglycemia was slower, as might be expected, in view of the slower liberation of sugar by the digestive processes. Fat or protein, in contrast with glucose or starch, were without effect on the level of the sugar in the blood; but when starch was administered along with fat the degree of the alimentary hyperglycemia was relatively mild. The explanation of the inhibitory effect of the fat on the tendency to hyperglycemia is presumably to be sought either in the fact that the presence of the fat mechanically interferes with the ready digestion of starch and consequent liberation and absorption of sugar, or that fat retards the discharge of contents from the stomach and delays absorption in this way.

Effects of a similar sort were observed also in the blood of diabetics fed as indicated before. There is a tendency, however, for a greater increase in the blood-sugar content to assert itself in the abnormal than in the normal persons after an identical intake of carbohydrate; and the same increment of blood-sugar in diabetics is far more likely to lead to glycosuria. In healthy persons, for example, the content of blood-sugar may be raised to 0.16 or 0.17 per cent., without inducing an elimination of glucose. In diabetics the consequences are exaggerated in every direction. The possession of these newer data will serve to orient us better in the direction of successful diagnosis on the basis of the information to be obtained for the estimation of the sugar-content of the blood under known or controlled conditions of diet.

OVARIAN TRANSPLANTATION

In 1909 and 1911, W. E. Castle and John C. Phillips[1] reported successful experiments made by them in ovarian transplantation in guinea-pigs. They now report a third successful transplantation as corroborating their theories and give the conclusions drawn from their observations. The conservatism of their previous reports renders their deductions especially significant.

In their first successful experiment the ovaries from a black guinea-pig were transplanted into a previously castrated white one, which, during one year, produced six black-coated young like the animal from which the ovaries were obtained, and entirely different from the white mother-pig. The most careful investigation disclosed no other factor than the transplanted ovaries which could have caused the phenomenon.

In the second successful experiment the color-factors were repeated. The ovaries from a colored guinea-pig were grafted on an albino, which bore a brown-eyed cream young one to an albino mate. The characteristics of the other young born to the albino pair were exactly such as would have been produced had the colored animal been mated with the albino male.

In the third successful experiment,[2] a different factor obtained. The animals mated were alike in all genetic features. The mother guinea-pig, of an agouti hair-pattern—the upper part of the body brownish with a mixture of red and black, the belly yellowish—received the ovaries from a light cinnamon animal. The reported result shows that "the sojourn and development in the body of a brown animal of an ovary taken from a cinnamon animal does not seem to have altered in any respect the initial genetic possibilities of the germinal substance."

The conclusion arrived at is that these three cases furnish substantial evidence in favor of Weismann's theory that in the higher animals the germinal substance and the body of the animal—that is, the germ-plasm and the soma—are physiologically distinct, and that the germ-plasm is not modified through somatic influences. The familiar formula "acquired characters are not transmitted," and the theory that happenings to the individual parent which do not affect the germ-plasm will not be transmitted to the offspring, thus receive, not, indeed, absolute proof, but strong confirmation.

[2] Castle, W. E., and Phillips, John C.: Further Experiments on Ovarian Transplantation in Guinea-Pigs, Science, Nov. 28, 1913, p. 783.

All this is of interest through the present tendency toward the framing of laws in accordance with the idea that the children of criminals, alcoholics or drug-slaves probably will inherit these undesirable qualities. Such qualities may be racial or familial and not due to the influences of one generation; but they do not inevitably appear in all members of the stock. Biology seems to give definite evidence that acquired qualities are not transmitted and that the temporary custodian of the germ-plasm cannot interfere with the family strain.

Our lack of definite knowledge concerning the large problems of heredity appears to be emphasized by these conclusions. Many defects due to factors which have affected the family germ-plasm are inherited, but there is no positive evidence that all parental qualities are likely to be inherited. In connection with the Mendelian principles of heredity, the cases reported by Castle and Phillips are of much deeper significance than their biologic interest.

These experimenters declare that the method is not practical for domestic animals or man unless the tolerance of the body to foreign tissue may be increased. Out of one hundred and forty-one female guinea-pigs engrafted with foreign ovaries, but three produced young. In eleven cases the original ovarian tissue was regenerated, the young in three of these cases showing the genetic character of the mother, but none of the graft. At necropsy in eighty-seven cases no ovarian tissue was found, as the transplanted ovaries failed to persist.

The experience of Castle and Phillips indicates that without careful investigation, reports of cases of successful ovarian transplantation in the human being must be viewed with suspicion, though it is suggested that an increased tolerance of the host may be secured by an immersion of the transplant-tissue for a time in a nutrient medium or in serum from the host. As yet, however, Castle and Phillips have not tried these methods.

DEATHS OF PHYSICIANS IN 1913

During 1913 the deaths of 2,196 physicians in the United States and the Dominion of Canada were noted in THE JOURNAL. Reckoning on a conservative estimate of 150,000 physicians, this is equivalent to an annual death-rate of 14.64 per thousand. For the eleven previous years the death-rates were as follows: 1912, 14.13; 1911, 15.32; 1910, 16.96; 1909, 16.26; 1908, 17.39; 1907, 16.01; 1906, 17.2; 1905, 16.36; 1904, 17.14; 1903, 13.73, and 1902, 14.74. The average annual mortality for the period from 1902 to 1913, inclusive, was therefore 15.82 per thousand. The chief death causes in the order named were senility, "heart disease," cerebral hemorrhage, pneumonia and nephritis. The age at death varied from 22 to 98, with an average of 59 years, 8 months and 12 days. The general average age at death since 1904 is 59 years, 7 months and 21 days. The number of years of practice varied from 1 to 73, the average being 32 years, 11 months and 7 days. The average for the past 10 years is 32 years, 7 months and 22 days.

CAUSES OF DEATH.—There were 253 deaths assigned to general diseases; 246 to diseases of the nervous system; 301 to diseases of the circulatory system; 166 to diseases of the respiratory system; 125 to diseases of the digestive system; 148 to diseases of the genito-urinary system; 298 to senility; 7 to diseases of the skin; 3 to diseases of bones; 43 to suicide; 101 to accident; 19 to homicide, and 82 to other causes. Among the principal assigned causes of death are senility, 298; "heart disease," 227; cerebral hemorrhage, 195; pneumonia, 150; nephritis, 140; accident, 101; after operation, 80; tuberculosis, 68; cancer, 54; suicide, 43; arteriosclerosis, 30; diabetes, 29; septicemia, 26; appendicitis, 25; angina pectoris, 23; gastritis, 21; homicide, 19; typhoid, 18; influenza and peritonitis, each 11; cirrhosis of liver, 10; anemia, mental alienation, myocarditis, gastric ulcer and cholecystitis, each 9; erysipelas and scarlet fever, each 8; meningitis and abscess, each 7; bronchitis and intestinal obstruction, each 6; diphtheria and prostatitis, each 5; locomotor ataxia, general paralysis of the insane, embolism, pleurisy, duodenal ulcer and enteritis, each 4; malaria, alcoholism, chorea and endocarditis, each 3; typhus fever, tetanus, rheumatism, aneurysm, hernia, mastoiditis and labor, each 2 deaths, and pertussis, syphilis, drug addiction, epilepsy, Hodgkin's disease and osteomyelitis, each 1 death.

The causes assigned for the 101 deaths from accident were: automobiles, 34; falls, 11; runaways, 10; poison, 9; drownings and railway, each 8; conflagrations and street cars, each 3; exposure, asphyxiation, crushing, sunstroke and strangulation, each 2, and burns, firearms, cutting instruments, explosion and electricity, each 1. The 43 physicians who ended their lives by suicide selected the following methods: firearms, 24; poison, 14; strangulation and cutting instruments, each 2, and jumping from high places, 1. Of the 19 homicides, 17 were due to firearms and 2 to clubbings or beatings. Of these, 5 occurred in feuds or affrays.

AGES.—Of the decedents, 68 were between the ages of 21 and 30; 213 between 31 and 40; 317 between 41 and 50; 419 between 51 and 60; 500 between 61 and 70; 399 between 71 and 80; 146 between 81 and 90, and 24 were more than 90 years of age. The greatest mortality occurred at the age of 63, when 70 deaths were recorded; at 68, with 60 deaths; at 66, with 56 deaths; at 60 with 55 deaths; at 73, with 51 deaths, and at 69 and 70, when 50 died. There were 9 deaths at 91; 5 at 92; 3 at 93; 2 each at 97 and 98, and 1 each at 94, 95 and 96.

Years of Practice.—By periods of 10 years the physicians died as follows: in the first decade, 197, of whom 4 had been in practice less than 1 year and 25 less than 2 years; in the second decade, 351; third decade, 465; fourth decade, 495; fifth decade, 424; sixth decade, 192; seventh decade, 60, and eighth decade, 3, two of whom had been in practice more than 73 years.

Military Service.—During the year, 258 died who had served in the Civil War, and of these, 72 followed the fortunes of the Lost Cause, 92 were medical officers of United States Volunteers and 2 were medical cadets. There were 3 veterans of the Mexican War; 19 had served in the Spanish-American War, 1 had served in Indian wars, 3 had been in the Indian Service, and 15 had seen service in foreign wars. The Army lost 29 medical officers, past and present, 4 officers of the Medical Reserve Corps on the active and inactive lists, and 13 acting assistant or contract surgeons. The Navy lost 14 medical officers, the Public Health Service 12 officers and the Organized Militia 30, of whom 11 had attained the grade of surgeon-general.

Medical Positions.—Medical colleges sustained the loss of 155 professors, lecturers, instructors and demonstrators; hospitals lost 280 members of staffs; municipalities, townships and counties, 150 health officers, and school boards or boards of education, 85 members. There were 25 deaths of members of state boards of health, medical registration and examination and charities; 45 of coroners and medical examiners, and 93 of railway surgeons.

Civil Positions.—Of those who died, 1 had been a member of Congress; 10 members of state senates; 32 members of the house of representatives; 44 had been mayors; 28 councilmen or aldermen; 41 had served in various civil official positions; 11 had been postmasters; 24 editors of medical or lay journals; 24 were also clergymen, of whom 14 were or had been foreign missionaries; 9 had been attorneys; 2 had been members of the diplomatic corps; 33 were bankers; 6 dentists; 16 pharmacists; 3 chemists, and 9 had been medical directors of life insurance companies or fraternal insurance societies.

THE HISTORY OF SPECTACLES

We have already given[1] an account of the discovery of the earliest known pair of spectacles, those belonging to Willibald Pirkheimer in the Wartburg, by Greeff of Berlin; more recently Greeff[2] has described a still earlier pair, probably made before the year 1500, which were brought to his attention by Sudhoff of Leipsic. These were found in an old volume of incunabula by the well-known antiquarian bookseller, Jacques Rosenthal, and were presented by him to the Germanic National Museum at Nuremberg, where they are now to be seen in the sections devoted to costumes and personal ornaments. The frame is of tanned blackened leather, of obvious Nuremberg make, and, like the Pirkheimer spectacles, of the old traditional "nose-rider" shape, but they are clumsier and thicker than the Pirkheimer pattern of 1520-1530. The lenses are lacking. In view of these characteristics and of the fact that they were found in an old fifteenth-century folio, Greeff and Sudhoff seem to have no doubt that they were made before 1500.

Greeff[3] also traces the evolution of the true modern spectacles from the old nose-riders (the originals of the pince-nez), and describes the binocles or *Scheerenbrillen* which came into fashion in 1796, consisting of two lenses mounted on a scissor-shaped handle, the originals of the modern lorgnette. The earliest form of the true spectacle glasses was invented and introduced by Monsieur Thomin, *marchand miroitier lunettier* of Paris, and were essentially "temple spectacles" (*lunettes à tempes*), the shanks extending no further than the temples. There were two kinds, one with a small end-platelet, which was represented in a portrait by Pelham, an English painter of the eighteenth century, of which a copper plate was made by J. Clark; the other, which is to be seen in Graff's portrait of Chodowiecki (1795), with a characteristic large circular fastener at the end of the shank, which held the spectacles against the temple. The next stage was that of the "ear spectacles," which at first had crude, heavy, clumsy shanks, jointed at the end, like those in the Beethoven house at Bonn, which were further improved by slitting the ends or by means of an olive-shaped fastener. The next improvement, consisting of a jointed appendage to the shank which passed underneath the occiput, was made in 1752 by the London optician J. Ayscough. A later variant of this joint passed downward and backward underneath the ear. Still another variety of this joint was so arranged that it could be bent suboccipitally, as in the first instance, but otherwise bent back *in extenso* when the glasses were not in use. These were called extension-spectacles (*Auszichbrillen*). Up to the beginning of the eighteenth century the lenses were still very large and round; but after that time they began to be octagonal, square, rectangular and finally oval. About the same time the bridge began to change in shape, first assuming the form of a K placed sidewise.

The origin of the present fashion of large circular lenses set in delicate tortoise-shell mounts is a pastel portrait of the painter Chardin in the Louvre, executed by himself in 1760, the spectacles in which were copied with great success by recent French opticians and are known in Paris as Chardin spectacles. The same type is familiar to us in a well-known portrait of Benjamin Franklin. Four or five years ago, says Greeff, a young woman or lady of fashion would have been horrified at the notion of wearing spectacles of such an unsightly type. To-day she would regard it as not only chic, but the height of elegance. Plenty of people in America are inclined, no doubt, to revive the traditions of "old Ben Franklin's days" for similar reasons, although the optical advantages and the comfort of these large lenses are obvious.

Current Comment

THE EFFECT OF PNEUMOTHORAX ON THE BLOOD

Attention has previously been called to the undeniable increase in the number of red blood-corpuscles and in the content of hemoglobin in the blood which life at higher altitudes calls forth in man.[1] The fundamental factor in bringing about this functional response is admitted to be the lowered partial pressure of the oxygen of the atmosphere at the higher levels. There are ways of decreasing the oxygen-obtaining capacity of the blood other than by diminution in the tension of the gas in the inspired air. The function of the inner lung-surfaces that are used in respiration can be limited decidedly by the production of a one-sided pneumothorax—a procedure which at present finds application in the domain of therapy. Under such circumstances the response of the blood-forming organs is quite comparable with what takes place at altitudes. The number of erythrocytes and the content of hemoglobin rapidly increase.[2] There are evidences that this is not the result of mere concentration of the blood-plasma; the blood picture as well as the analytic data clearly suggest a new formation of the blood components concerned in the oxygen-carrying function. It would appear, therefore, that it matters little how a deficiency of respired oxygen is threatened in the body; the response in the way of compensatory processes such as are represented in the regeneration or new formation of blood-cells and pigment is prompt and characteristic.

THE SYNTHETIC CAPACITIES OF BACTERIA

There is constantly growing evidence that the animal organism is capable of synthetic activities which were scarcely appreciated or in any way anticipated a generation ago, when such powers were relegated almost exclusively to the domain of plant performances. Nevertheless it is likewise becoming clear that however important and effective these constructive functions of the animal cells may prove to be, they have certain limitations which render them incapable of meeting in a synthetic way all the demands which nutritive emergencies put on them from time to time. From observations of Abderhalden, Osborne and Mendel, and others, it appears that lack of cyclic groups, such as are represented by tyrosin, tryptophan and phenylalanin in the ordinary proteins, leads to nutritive failure, which cannot be remedied by constructive functions on the part of the organism suffering from a loss of these aromatic amino-acids. For this reason gelatin, for example, being deficient in the cyclic "building-stones," fails to satisfy the protein requirements of the animal body completely. Plants, of course, construct the cyclic derivatives readily from elementary compounds. The supreme synthetic efficiency of the vegetable organism is shown in the production of the familiar alkaloids which afford exquisite illustrations of the type of substance referred to. The bacteria, which are commonly classed with plant forms, are likewise known to exhibit synthetic capacities and to construct their own complex protoplasm in relatively simple nutrient mediums. Whether or not this power of synthesis actually includes the ability to construct cyclic compounds like tyrosin, etc., has been answered in a positive sense by recent experiments of Tamura.[1] By growing bacteria in solutions devoid of any organic substances other than lactic acid, glycerol and asparagin, he has obtained an abundant "crop" of micro-organisms, which, on analysis, exhibited the presence of the nitrogenous phosphatids, purin bases and proteins in abundance. The new construction of the cyclic aromatic fragments of the proteins, so difficult to demonstrate in the animal organism, is thus shown to proceed with ease in the metabolism of the bacteria.

AN ORDINANCE TO PUNISH MISLEADING ADVERTISING

Following the recent exposure in Chicago of quack doctors, who exist there, as elsewhere, only by virtue of the use of the newspapers, the city council has passed an ordinance intended to prevent false and misleading newspaper advertising in Chicago. It follows closely the *Printers' Ink* bill, which, with modifications, has already been enacted into law in sixteen states.[2] The statute not only reaches the quack who depends on newspaper advertising for the prosperity of his swindling operations, but is also sufficiently broad to cover other fraudulent advertising, in particular, advertisements of fake auctions, fire sales, bankrupt sales, etc. It forbids the publication of any "advertising which contains assertion, representation or statement which is untrue, deceptive or misleading."

Simple Mind or Mediocre.—Simple minds are contented with mystic solutions, with an illusory play of words. Men of science investigate with an open mind, are satisfied with their work, which, if slow, is certainly progressive. But the mediocre mind wishes to know everything without much trouble, and has a strange longing for prompt and safe formulae. Such men are the predestined victims of prejudice and scientific quackery.—Lugaro, Problems in Psychiatry.

Medical News

ILLINOIS

Personal.—Dr. Alonzo B. Middleton, Pontiac, left January 1 for Europe.——Dr. Clinton Helm, Rockford, who has been ill for a long time, is reported to be slowly improving.——Dr. Charles E. Sisson, Elgin, is reported to be seriously ill with scarlet fever.——Dr. L. S. Gabby of the Kankakee State Hospital will assume charge, some time this month, of the pathologic and research laboratory established and equipped by Drs. O. L. Pelton, Sr., and Jr., of Elgin.——Dr. Cyrus W. Rutherford has been appointed local surgeon for the Cincinnati, Hamilton and Dayton Railway at Newman.

Promotional Examination.—At a promotional civil examination held November 28 for members of the Cook County Hospital staff the following received positions as chief attending physicians and surgeons: Dr. Joseph A. Capps, department of medicine; Dr. E. Wyllys Andrews, department of surgery; Dr. Henry F. Lewis, department of obstetrics; Dr. Channing W. Barrett, department of gynecology; Dr. H. Bascom Thomas, department of orthopedics; Dr. Clifford G. Grulee, department of pediatrics; Dr. Stanton A. Friedberg, department of diseases of the ear, nose and throat; Dr. George F. Suker, department of diseases of the eye, and Dr. Frederick G. Harris, department of skin and venereal diseases, all of Chicago.

Chicago

Nurses' Home Opens.—The Home of the Training School for Nurses of the Presbyterian Hospital, erected at the cost of $365,000 as a memorial to the late Otho S. A. Sprague, was opened informally, December 31. The building is a seven-story structure opposite the hospital and connected with it by a tunnel and contains class rooms, demonstration rooms, laboratory, etc., and has accommodation for 160 nurses.

Personal.—Dr. L. Blake Baldwin has returned after a year spent as ship surgeon on transpacific steamers.——Dr John E. Owens, for more than twenty-five years chief surgeon of the Chicago and Northwestern System, has been appointed consulting surgeon of the road and Dr. Clarence W. Hopkins has been promoted to chief surgeon.——Dr. Samuel D. Nixon was seriously injured in a collision of his motor car and a Baltimore and Ohio train at an unguarded grade crossing, December 28.

Meeting of Alienists and Neurologists.—The Chicago Medical Society will hold its third annual conference with the alienists and neurologists of the United States, July 14 to 18. The object is to have a scientific program, including research work which will be of benefit to every physician whether in general practice or connected with an asylum or sanatorium. One day is to be devoted to a public meeting at which the prevention of insanity and the conditions causing mental defectives will be discussed. At this session resolutions will be introduced for the framing of such laws as will, in a reasonable measure, prevent these conditions, and these resolutions will be presented for consideration to the various state legislators and national governors. The Committee on What Constitutes a Modern Hospital or Asylum and What are the Duties of the State to the Physician makes the care of the insane and mental defectives a specialty, and will present its report. Superintendents and members of the attending staff of the state hospitals and sanatoriums and neurologists are invited to participate in this meeting. Communications should be addressed to the secretary, Dr. W. T. Mefford, 2129 West Madison Street.

Appropriations and Increase in Infectious Diseases.—The commissioner of health of Chicago, in presenting the budget of the requirements of the health department for the year 1914, calls attention to the fact that the financing of the various bureaus has not kept pace with the problems connected with the control of contagious diseases and the increased growth of the city. This refers chiefly to the inspection department, and the result is seen in the figures, which show an increase in practically all of the contagious diseases for the year 1913. Among the diseases which affect chiefly children, the figures for the first eleven months of 1913 are as follows: Measles, 14,986 reported cases and 286 deaths; increases over 1912 of 155 per cent. in cases, and 94 per cent. in deaths. Scarlet fever, 10,136 reported cases and 876 deaths; increases of 32 per cent. in cases and 71 per cent. in deaths. Diphtheria cases reported, 7,781; deaths, 886; increases of 24 per cent. in cases and 8 per cent. in deaths. Increases among the less fatal diseases of childhood are: 718 chicken-pox, 434 mumps and 240 German measles. Among those diseases which menace, chiefly, adult life there are notable increases as follows: typhoid fever cases reported, 1,385; deaths, 218; increase of 42 per cent. and 35 per cent. respectively. Small-pox cases reported, 67 increase; deaths show a decrease of 5. Tuberculosis cases reported, 1,772 increase; deaths, 101 increase. The respective increases are 26 per cent. and 3 per cent. Pneumonia and influenza also show slight increases. It is said that better control of milk and other foodstuffs, housing and ventilation will go a long way toward reducing these diseases to a minimum. Largely increased appropriations for 1914 have therefore been insisted on. At present Chicago spends about 1.5 per cent. of its total appropriation of $60,000.000 for health purposes, a smaller percentage than any other large city in the United States.

INDIANA

Quarantine Removed.—The Wabash Employees Hospital, Ridgeview, which has been under quarantine on account of a case of small-pox for more than a month, has been reopened.

Wishard Memorial Meeting.—At a meeting of the Indianapolis Medical Society, December 11, the session was devoted to addresses in recognition of the life and work of the late Dr. William Henry Wishard. Memorial resolutions were adopted and a committee was appointed to prepare a special memorial on the life and services of Dr. Wishard.

Tuberculosis Items.—A camp for the treatment of persons affected or afflicted with tuberculosis has been given by the commissioners of St. Joseph County as a Christmas gift to the county, covering a site of 30 acres, to which 60 acres will be added and cottages will be constructed as soon as spring opens.——Work was commenced December 12 on the construction of two tuberculosis open-air dwellings to be placed for exhibition purposes in the courthouse square at Lafayette.

Hospital News.—The balance of the funds collected in Indiana for flood sufferers, which amounted to $1,116, has been devoted toward the fund for the maintenance of a hospital in Shelbyville.——A cancer hospital is to be established in Indianapolis by the Peoples Union. There will be a free clinic in connection with the institution. Dr. Thomas C. Kennedy will be superintendent of the hospital; Dr. J. W. Duckworth, assistant superintendent, and Dr. Orvall Smiley, pathologist.

Personal.—Dr. Charles S. Woods, formerly city sanitarian of Indianapolis, has accepted the professorship of preventive medicine in the University of Iowa and moved to Iowa City, December 28, to take up his new duties.——Dr. Joseph W. Patterson, Fairmount, is reported to be critically ill with disease of the kidney.——Dr. John H. Luken, Richmond, while riding a bicycle, December 23, collided with an automobile and was painfully injured.——Dr. A. C. Shauck, Arlington, was thrown from a motorcycle, December 19, and sustained painful cuts and bruises.——Dr. Christian B. Stemen, Fort Wayne, who has been seriously ill for several months, is now reported to be convalescing.

New Officers.—Miami County Medical Society at Peru, December 26: president, Dr. Homer E. Line, Chili; secretary-treasurer, Dr. Martin A. McDowell, Peru.——Grant County Medical Society at Marion, December 24: president, Dr. Glen D. Kimball; secretary, Dr. James E. Johnson, both of Marion.——Vanderburg County Medical Society at Evansville, December 23: president, Dr. Gardner C. Johnson; secretary-treasurer, Dr. Clarence A. Hartley, both of Evansville.——Tippecanoe County Medical Society at Lafayette, December 23: president, Dr. Robert M. Campbell; secretary, Dr. Earl Van Reed, both of Lafayette.——Owen County Medical Association at Gosport, December 19: president, Dr. George L. Mitchell, Quincy; secretary, Dr. Allen Pierson, Spencer.——Elkhart Academy of Medicine, December 18: president, Dr. James A. Work, Jr.; secretary-treasurer, Dr. Hannah O. Staufft.——Clay County Medical Society at Brazil, December 18: president, Dr. Melvin H. Young, Harmony; secretary-treasurer, Dr. Frederick C. Dilley, Brazil.——Kosciusko County Medical Society at Warsaw, December 12: president, Dr. Charles A. Thomas, Leesburg; secretary-treasurer, Dr. Forrest J. Young, Milford.——Greene County Medical Society at Linton, December 18: president, Dr. Benjamin F. Chambers, Lyons; secretary-treasurer, Dr. Elias R. Mason, Bloomfield.——Laporte County Medical Society at Laporte, December 12: president, Dr. Dexter A. Buck; secretary, Dr. Harvey H. Martin, both of Laporte.——Bartholomew County Medical Association at Columbus, December 9: president, Dr. Herman H. Kamman; secretary-treasurer, Dr. Elmer U. Wood, both of Columbus.——Lake County Medical Society at Hammond, December 9: president, John W. Iddings, Lowell; secretary-treasurer, Dr. Eldridge M. Shanklin, Hammond.——Clinton County Medical Society at Frankfort, December 4: president, Dr. John C. Robinson, Geetingsville; secretary-treasurer, Dr. Archibald Golding Chittick, Frankfort (reelected).

IOWA

Personal.—Dr. Ulysses G. Grigsby, Perry, has resumed practice after a serious illness of several weeks.——Dr. Samuel D. Tobey, Council Bluffs, who was seized with cerebral hemorrhage December 5, is said to be improving at the Jennie Edmondson Memorial Hospital.

Hospital News.—Des Moines General Hospital will open a new free dispensary this month.——The new Contagious Hospital erected by Des Moines adjoining the Small-Pox Hospital is complete, but still lacks equipment.——The tuberculosis sanatorium for Polk County at the county farm near Saylorsville, is ready for occupancy. The building will accommodate twenty patients.

New Officers.—Hardin County Medical Association at Eldora; president, Dr. Frank Siedenburg, Alden; secretary, Dr. Nathan C. Morse, Eldora.——Polk County Medical Society at Des Moines, December 23: president, Dr. Granville N. Ryan; secretary, Dr. Thomas F. Duhigg (reelected), both of Des Moines.——Decatur County Medical Society at Leon, December 12: president, Dr. Jesse S. Coontz; secretary-treasurer, Dr. William E. Lyons, both of Garden Grove.——Page County Medical Society at Shenandoah, December 18: president, Dr. Robert J. Matthews, Clarinda; secretary, Dr. B. S. Barnes, Shenandoah.——Floyd County Medical Society at Charles City, December 19: president, Dr. Charles J. O'Keefe, Marble Rock; secretary-treasurer, Dr. Charles O. Yenerich, Rockford.——Union County Medical Society at Creston, December 17: president, Dr. J. W. Fry; secretary, Dr. Thomas V. Golden, both of Creston (reelected).——Taylor County Medical Society at Bedford, December 15: president, Dr. Henry F. Dunlavy; secretary-treasurer, Dr. Clayton M. Paschal, both of Bedford.——Wright County Medical Society at Clarion, December 17: president, Dr. Thomas J. O'Toole; secretary, Dr. William C. McGrath, both of Eagle Grove.——Greene County Medical Society at Jefferson, December 11: president, Dr. George W. Kester, Grand Junction; secretary-treasurer, Dr. Benjamin C. Hamilton, Jr., Jefferson.——Washington County Medical Society at Washington, December 16: president, Dr. Marcus C. Terry, Brighton; secretary-treasurer, Dr. Clyde A. Boice, Washington.——Iowa County Medical Society at Marengo, December 11: president, Dr. Chas. F. Noe, Amana; secretary, Dr. George F. Schug, Williamsburg.——Burlington Medical Society, December 10: president, Dr. Albert C. Moerke; secretary, Dr. E. A. Hunt.

NEW YORK

Sanatoriums Wanted.—Citizens of Lyons Falls and vicinity appealed to the board of supervisors of Lewis County to take immediate steps to establish a county hospital for tuberculosis.——Chenango County is the twenty-ninth county in the state to vote for the establishment of a county hospital for tuberculosis.——The tuberculosis sanatorium established by the Metropolitan Life Insurance Company on Mount MacGregor for the care of its employees is completed and receiving its first patients. Dr. Horace J. Houk is the physician in charge of the institution.

New Officers.—Lewis County Medical Society at Lowville, December 9: president, Dr. Ira D. Spencer, Croghan; secretary, Dr. Edward N. K. Mears, Lowville.——Chautauqua Medical Association at Dunkirk, December 9: president, Dr. George F. Smith, Falconer; secretary-treasurer, Dr. Josiah W. Morris, Jamestown.——Chenango County Medical Society at Norwich, December 10: president, Dr. John D. T. Hand, New Berlin; secretary, Dr. Paul B. Brooks, Norwich.——Schoharie County Medical Society at Cobleskill December 9: president, Dr. Carolyn L. Olendorf, Cobleskill; secretary, Dr. Herbert L. Odell.

Personal.—Dr. Norman H. Soble, a member of the police commission of Elmira, has been appointed a member of the board of managers of the State Tuberculosis Hospital.——Dr. Joseph D. Craig, for fourteen years health officer of Albany, has retired from that position, and on December 30 was presented by the employees of the office with a loving cup.——A dinner was given by the physicians of Syracuse, December 30, to the outgoing health officer, Dr. David M. Totman, and the incoming health officer, Dr. Frederick W. Sears.——In the case of George E. Kusnezsky against Dr. George E. Smith, Fredonia, who was sued for $2,000 for alleged malpractice, a verdict of "no cause for action" was returned by the jury, December 24.——Dr. Arthur H. Brown, Auburn, gave a dinner to the medical profession of Cayuga County December 23 in honor of the thirtieth anniversary of his practice in the city. Dr. John D. Tripp, on behalf of the physicians present, surprised Dr. Brown by presenting him with a silver loving-cup.——Dr. and Mrs. Jacob J. Levy, Syracuse, have returned from Europe.

New York City

Cancer Laboratory Ready.—The Crocker Research Cancer Laboratory at Columbia University has been completed and turned over to the commission headed by Dr. Frances Carter Wood, which will begin its work this month. The building is three stories and a basement in height and 100 by 35 feet.

New Officers.—Caledonian Medical Society, fourth annual meeting, in Brooklyn, December 29: president, Dr. William J. Cruikshank; secretary-treasurer, Dr. Sutherland Miller, both of Brooklyn.——Medical Society of the County of Kings, ninety-third annual meeting, at Brooklyn, December 16: president, Dr. J. Richard Kevin; secretary, Dr. Burton S. Harris.

Personal.—Dr. Livingston Farrand, executive secretary of the National Association for the Prevention of Tuberculosis, has resigned to become president of the University of Colorado.——Dr. L. Emmett Holt, who was operated on for appendicitis at his home December 15, is convalescent.——Dr. Harold W. Wright, formerly of Bellevue Hospital, has located in Santa Barbara, Cal.

OHIO

Sanatorium to Be Removed.—The Cleveland City Tuberculosis Hospital is to be moved to Warrenville, where it will be conducted with other antituberculosis industries under the supervision of Dr. Robert H. Bishop, Cleveland.

Scarlet Fever in Cleveland Hospital.—There has been a severe outbreak of scarlet fever at Huron Road Hospital which necessitated the quarantining of the institution. Mr. Ray Ewark Parks, a senior student in the medical department of the Western Reserve Medical College, died from the disease December 13, and Dr. R. L. Allen, one of the house staff, a nurse and an orderly are also ill with the disease.

Personal.—Drs. Paul J. Hanzlik and Howard Lester Taylor of Cleveland have started for Europe.——Dr. James H. Hewitt, Cleveland, has been appointed resident pathologist of the Cleveland City Hospital.——Dr. Clyde E. Ford has been appointed executive head of the Cleveland Health Department and Dr. Martin Friedrich medical expert of the department.——Drs. Harry S. Davidson and James G. Grant, Akron, whose offices in the Woods Building recently burned, have opened offices in the Everett Building.——Drs. Oscar S. Cox McArthur and Clinton J. Altmaier, Columbus, have been appointed as assistant medical examiners for the Workman's Compensation Department of the State Industrial Commission.——Dr. William H. Begg, Columbus Grove, was recently operated on for goiter in a hospital in Toledo.

New Officers.—Celsus Club at Akron: president, Dr. Dell S. Bowman; secretary-treasurer, Dr. Charles E. Norris.——Barberton Medical Association: president, Dr. William A. Hansfield; secretary-treasurer, Dr. Herbert A. Rodenbaugh.——Cleveland Academy of Medicine: president, Dr. John J. Thomas; secretary-treasurer, Dr. Jacob E. Tuckerman.——Cleveland Medical Library Association: president, Dr. Benjamin L. Millikin; secretary, Dr. Henry L. Sanford.——Clermont County Medical Association at Milford, December 17: president, Dr. Frank H. Lever, Loveland; secretary, Dr. Frank A. Ireton, Newtonsville.——Richland County Medical Society at Mansfield, December 24: president, Dr. John Maglott; secretary-treasurer, Dr. Julia Lillian McBride, both of Mansfield.——Columbus Academy of Medicine, twenty-second annual meeting, December 15: president, Dr. Fred Fletcher; secretary, Dr. Roscoe R. Kahle.——Mahoning County Medical Society at Youngstown, December 16: president, Dr. Charles D. Houser; secretary, Dr. Harry E. Patrick, both of Youngstown.——Fairfield County Medical Society at Lancaster, December 16: president, Dr. George S. Courtright, Lithopolis; secretary-treasurer, Dr. Henson M. Hazelton, Lancaster.——Knox County Medical Society at Mount Vernon, December 10: president, Dr. Irvin S. Workman, Mount Vernon; secretary-treasurer, Dr. Ernest V. Ackerman, Fredericktown.——Van Wert County Medical Society at Van Wert, December 8: president, Dr. Martin Cramer; secretary-treasurer, Dr. Charles G. Church, both of Van Wert.——Greene County Medical Society at Xenia, December 4: president, Dr. Clarence G. McPherson; secretary, Dr. David E. Spahr, both of Xenia.——Drake County Medical Society at Greenville, December 11: president, Dr. Jacob C. Poling, Ansonia; secretary-treasurer, Dr. John E. Hunter, Greenville.——Hancock County Medical

Society at Findlay, December 4: president, Dr. Robert B. Taylor, Arcadia; secretary, Dr. Nelia B. Kennedy (reelected), both of Findlay. The society presented to Dr. Kennedy a silver loving cup in appreciation of her service as secretary of the organization.

Cincinnati

Library Enlarged.—The library of the Medical School of Cincinnati has been greatly increased during the past year, both by donation and purchases. It is under the charge of Miss Frances, secretary of the Medical Library of the University.

Visiting Nurses' Activities.—A movement is on foot in Cincinnati whereby the benefits of the visiting nurses may be extended to the middle class, who will be expected to pay a moderate price for services rendered.——The Visiting Nurses' Association collected $8,000 by its recent leadpencil sale.

Cincinnati Women's Medical Society.—This society, which was organized only a year ago, has grown into an active and flourishing medical body. It has in contemplation the establishment of a new lying-in hospital for the accommodation of the middle classes and it is said that the building of the Ohio Maternity Hospital may be employed for this purpose.

University Instals New Dean.—The University of Cincinnati will celebrate the installation of Dr. Christian R. Holmes as dean of the Medical College January 16. Dr. William Henry Welch, professor of pathology at Johns Hopkins University Medical School, Baltimore, and acting president of that university, will make the address of the occasion. Dr. Welch is the greatest authority in America on medical education and the object of this celebration is to call attention to the advance in the standards of the medical colleges throughout the country and especially the standards of admission thereto. During the last five years the great majority of the proprietary medical schools have been eliminated or united with the universities. The university medical college is now recognized as the highest type of medical school, and it is believed that after a few years it will be the only type in this country. Since the union of the medical colleges with the universities their standards have been greatly advanced. The first step has been to put all of the fundamental scientific departments in charge of full time professors instead of practitioners, as in the older colleges. These men devote all of their time to teaching and research work in the medical sciences. The next step was to advance the standards of admission. The Council on Education of the American Medical Association, which has led in the campaign for these improvements, now announces that sixty of the medical colleges in this country already require college preparation for entrance, and that by 1915 this number will be increased to eighty. This makes it necessary that the academic institutions shall establish courses in sciences and languages to prepare students to study medicine. In view of this situation the medical faculty of the University of Cincinnati has arranged to hold on January 17 a conference of presidents and professors of academic institutions with the deans and professors of the medical schools on the subject of preparatory medical education. Representatives of both these classes of institutions are cordially invited to attend the celebration as well as the conference. A very interesting program has been arranged, including a visitation of the new hospital and laboratories of the Cincinnati University Medical College and luncheon at the University, followed by a conference meeting and a dinner at the Business Men's Club.

OKLAHOMA

Hospital Notes.—The new State Hospital for the Insane at Vinita is rapidly nearing completion.——Physicians of Durant have completed plans for the erection of a new hospital in that city.

Tuberculosis Notes.—The Oklahoma Association for the Study and Prevention of Tuberculosis has been put in operation at Oklahoma City without capital stock by Drs. Curtis R. Day, John W. Riley and John C. Mahr.

Hospital for Indians at Lawton.—Congressman Scott Ferris has secured an appropriation of $40,000 from congress for the erection of an Indian Hospital at Lawton, to be maintained by the interest on $275,000 recently obtained from the sale of tracts of Indian lands in Kiowa, Comanche, Apache and Wichita reservations in the state.

Personal.—Dr. William R. Bevan, Oklahoma City, is spend-

Drs. Littleton A. Newton and C. B. Parker, Guthrie, have been appointed as examiners of the public school pupils of Guthrie.——Dr. Edward D. James, Haileyville, has been appointed physician of Pittsburg County, vice Dr. H. E. Williams, removed.——Dr. and Mrs. Walter M. Jones, Enid, were the guests of honor at a banquet, December 12, given by the members of the Garfield County Medical Society.——Dr. and Mrs. Jones have left for San Francisco.

New Officers.—Kay County Medical Association at Blackwell, December 10: president, Dr. H. M. Stricklen, Tonkana; secretary-treasurer, Dr. Edgar J. Orvis, Blackwell.——Muskogee Medical Society, December 8: president, Dr. J. Hutchings White; secretary-treasurer, Dr. Benjamin H. Brown.——Pittsburg County Medical Society at McAlester, December 4: president, Dr. James C. Johnston; secretary-treasurer, Dr. Leonard S. Willour, both of McAlester.——Grady County Medical Society at Chickasha, December 5: president, Dr. Robert J. Baze; secretary, Dr. William H. Cook, both of Chickasha.

PENNSYLVANIA

New Officers.—Columbia County Medical Society at Bloomsburg, December 12: president, Dr. Joseph Cohen, Berwick; secretary-treasurer, Dr. Luther B. Kline, Catawissa (reelected).——Shamokin Medical Society, December 12: president, Dr. Clarence M. Malone; secretary, Dr. Henry T. Simmonds.

Home for Incurables Recommended.—In the annual report of General Agent Wharton to the State Board of Public Charities he recommends that serious consideration be given to the establishment of a state institution especially devoted to the care of incurable diseases, such as cancer and other wasting disorders.

Personal.—Dr. J. R. Burns, Luzerne, has been appointed a member of the staff of the Scranton State Hospital.——Dr. John C. McMillen, Barnesboro, who has been ill for several months with nephritis at the Spangler Hospital is reported to be improving.——Dr. Joseph S. Kowaleski, Shamokin, who has been seriously ill at the Jefferson Hospital, Philadelphia, with septicemia, due to an operation wound, has returned home convalescent.

New Hospital for Pittsburgh.—Contracts for the erection of the New Elizabeth Steel Magee Hospital, memorial of the late Hon. Christopher L. Magee to his mother, were let December 21. The building will be erected on a 10-acre lot, and will consist of a central building with five wings, each four stories in height, and will accommodate 120 adult patients in wards, twenty-one in private rooms and about eighty babies. The contract price is $600,000, and the equipment will necessitate the expenditure of at least an additional $50,000. The hospital will be chiefly for maternity cases, but will also have a well-equipped gynecologic department. Dr. Charles Edward Ziegler is to be director of the hospital.

Spring City Home to Treat Girls.—The newly elected officers and directors of the Eastern Pennsylvania State Institution for Feeble-Minded and Epileptics, Spring City, have adopted plans for the erection of two new buildings, for the care of girls under 21 years of age. This institution, organized in 1907, was originally intended to accommodate boys and girls, but the old board decided it would first take care of boys. The two new buildings for the exclusive use of girls will be built on the college plan with connecting corridors and subways, and will accommodate two hundred and twenty patients. The board also took over an adjoining farm of 70 acres, making 181 acres purchased since Jan. 1, 1913, now giving the institution a total of 470 acres. The last legislature appropriated $579,450 for the institution.

Philadelphia

Eugenics Law Does Not Decrease Marriage.—The new eugenics marriage law had no deterring influence on the number of marriages in this city, as there were 16,122 licenses issued in Philadelphia during 1913, as compared with 15,365 in 1912.

Rush Society Lecture.—The sixth Rush Society lecture will be delivered by Prof. Dr. Sven G. Hedin of the University of Upsala, Sweden, at the College of Physicians, Twenty-Second and Chestnut Streets, January 27, at 8:30 p. m., on "Colloidal Reactions and Their Relations to Biology."

Coroner's Statistics.—According to the records of the coroner's office there was an average of one murder in every five days during the year 1913. Forty-eight persons were killed by automobiles and three deaths resulted from motorcycle accidents. There were sixty-six deaths from trolleys and eighty-six lives were lost in railroad accidents.

Bureau of Health Report.—Vital statistics of the Department of Health for the year 1913 show that the number of deaths from all causes were 25,602, as compared with 24,215 in the year previous, thus increasing the death rate from 15.08 to 15.69 per 1,000. Tuberculosis caused the greatest number of deaths. The total number of communicable diseases reported was 35,457, as compared with 23,170 in 1912.

Personal.—Dr. Joseph S. Neff, director of the Department of Public Health and Charities, who has been ill for several days, is reported to be improving.——Dr. Charles S. Hirsch has been appointed urologist at Mount Sinai Hospital and genito-urinary surgeon to the Lebanon Hospital.——Dr. Charles W. LeFever has been appointed ophthalmologist to the Mount Sinai Hospital.——Dr. William W. Keen was elected president of the American Philosophical Society, January 2.

Fund for Cancer Study.—Mrs. Lucy Henderson of New Castle, Pa., has donated a sum to the Jefferson Hospital, the income of which is to be used in studying cures for cancer with special emphasis on the use of radium. The yearly income will approximate $3,500 and the fund will be known as the Lucy Henderson Foundation. The work of investigation for which the donation has been made will be carried on under the direction of Drs. J. Chalmers DaCosta, W. M. Late Coplin and Hobart Amory Hare.

New Officers.—Philadelphia Medical Examiners' Association: president, Dr. Foster K. Collins; secretary, Dr. J. Lawrence Fisenberg, Norristown.——West Philadelphia Medical Association: president, Dr. Christian B. Longenecker; corresponding secretary, Dr. Henry G. Munson.——Northern Medical Association: president, Dr. Thomas Shriner; secretary, Dr. Victor A. Loeb.——Southeastern Branch of the Philadelphia County Medical Society: chairman, Dr. Simon Wendkos; clerk, Dr. Morris Ginsburg.——Section on Otology and Laryngology of the College of Physicians: chairman, Dr. George Morley Marshall; clerk, Dr. Benjamin B. Parish.——Germantown Branch of Philadelphia County Medical Society, December 22: chairman, Dr. Harry B. Wilmer.

TEXAS

Personal.—Dr. Henry Winston Harper, professor of chemistry in the University of Texas, Austin, was made first dean of the graduate department, December 10.——Dr. Joseph B. McKnight, Brady, on December 17, was appointed superintendent of the State Tuberculosis Sanatorium, Carlsbad, vice Dr. Bascom Lynn, resigned.

New Officers.—Hardeman County Medical Society at Quanah, December 26: president, Dr. John J. Hanna; secretary-treasurer, Dr. Thomas D. Frizzell, both of Quanah.——Bexar County Medical Society at San Antonio, December 18: president, Dr. Charles D. Dixon; secretary, Dr. W. H. Hargis.——North Texas District Medical Association, sixty-eighth annual meeting, at Fort Worth, December 9 and 10: president, Dr. K. Herberden Beall, Fort Worth; secretary, Dr. H. Leslie Moore, Dallas.——Tarrant County Medical Association at Fort Worth, December 22: president, Dr. Samuel A. Woodward; secretary, Dr. Frank G. Sanders (reelected), both of Fort Worth.——Aunis Physicians' Club, organized December 19: president, Dr. Charles H. Breuer, Waco; secretary, Dr. Walter P. McCall, Ennis.——Ellis County Medical Society at Waxahachie: president, Dr. Zachary R. Bundy, Austin; secretary-treasurer, Dr. Edgar F. Gough, Waxahachie.——Pecos, Ward and Reeves Counties Medical Society at Pecos, December 14: president, Dr. William H. Benway; secretary, Dr. Otis J. Bryan, both of Pecos.——Hunt County Medical Association at Greenville, December 16: president, Dr. D. Richard Waddle, Greenville; secretary, Dr. Harry M. Bradford.——McLennan County Medical Society at Waco, December 2: president, Dr. James M. Witt; secretary-treasurer, Dr. Doyle L. Eastland, both of Waco.——Dallas County Medical Society at Dallas, December 1: president, Dr. Calvin R. Hannah; secretary, Dr. Royal S. Loving (reelected).

GENERAL

American Medical Association.—The annual session of the American Medical Association for 1914 will be held in Atlantic City. The House of Delegates will convene on Monday, June 22, and the Scientific Assembly — the sections — on June 23.

Fraternity Election.—The grand chapter of the Phi Chi Medical Fraternity, at its meeting in St. Louis, December 31, selected Richmond, Va., as the next place of meeting and elected the following officers: presiding senior, Dr. Charles H. Hibbitt, Louisville, Ky.; presiding junior, Dr. Paul Maher, St. Louis; secretary-treasurer, Dr. Dunning S. Wilson, Louisville, Ky., and editor-in-chief of the Phi Chi Quarterly, Dr. T. B. Pearson, Wilmore, Ky.

Bequests and Donations.—The following bequests and donations have recently been announced:

Frisbie Memorial Hospital, Rochester, N. H., about $25,000 for the endowment of a hospital by the will of Dr. J. F. Frisbie, Newton, Mass.

Jefferson County (Ala.) Antituberculosis Association, $2,500 to be used in an organized effort to relieve tuberculosis in Jefferson County by the will of Wilson R. Brown.

Various Jewish charitable institutions of Philadelphia, $2,300 by the will of the late Judith L. Freshie.

We Repeat This Warning.—A this time of the year the ubiquitous subscription swindler is abroad working a nefarious game in making collections from unsuspecting victims, as payment for new and renewed subscriptions to THE JOURNAL. Information has been received that certain individuals are working the medical profession in Ohio, Indiana, Tennessee and Kentucky. By next week these swindlers will probably have migrated to some other territory. Our readers are therefore cautioned to pay money to no one unless the proper credentials are produced. Letters of authority bearing the signature of George H. Simmons and the official seal of the American Medical Association are supplied to the A. M. A.'s representatives. The holders of such letters are the only ones authorized to make collections. Information by telegraph regarding any of these swindlers will be welcome.

A Tennessee physician describes a certain Walter Thorne, claiming to be our agent in Tennessee, but of whom we have no knowledge, as follows: About 5 ft. 10 in., slender, age 22 years, black hair and black eyes. Extremely immature and boyish looking. Slight defect in speech due to absence of right upper median incisor tooth; left upper incisor tooth replaced by gold tooth.

Biologic Federation Meeting.—At the annual meeting of the Federation of American Societies for Experimental Biology, an organization which includes the Physiological Society, the Society of Biological Chemistry and the Society for Pharmacological and Experimental Therapeutics, held in Philadelphia, December 21 to 31, the following officers were elected: president, Dr. Graham Lusk, New York City; vice-president, Dr. Carl Alsberg, Washington, D. C.; secretary, Dr. P. A. Shaffer, St. Louis; treasurer, Dr. D. D. Van Slyke, New York City, and councilors, Prof. J. J. Abel, Baltimore, and Prof. A. B. Macallum and Dr. T. B. Osborne, New Haven, Conn.——Of the component societies, the Physiologic Society elected Dr. W. B. Cannon, Harvard, president; Dr. A. J. Carlson, Chicago, secretary, and Dr. J. Erlander, St. Louis, treasurer; the Biological Society elected Dr. R. M. Morse, Philadelphia, president; Surgeon John F. Anderson, U. S. P. H. S., Washington, D. C., vice-president; Dr. George H. Whipple, Baltimore, secretary-treasurer, and Drs. Harvey Cushing, Boston, and David Marine, Cleveland, councilors; the Pharmacological Society elected Dr. Torald Sollmann, Cleveland, president; Dr. J. Auer, New York City, secretary; Dr. W. DeB. MacNider, New York City, treasurer, and Dr. Reid Hunt, New York City, chairman of the membership committee.

Resolutions on Animal Experimentation.—At its meeting in Philadelphia, December 31, 1913, the Federation of American Societies for Experimental Biology adopted the following resolutions:

1. We, the members of the Federation of American Societies for Experimental Biology—comprising the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, and the American Society for Experimental Pathology—in convention assembled, hereby express our accord with the declaration of the recent International Medical Congress and other authoritative medical organizations, in favor of the scientific method designated properly animal experimentation but sometimes vivisection.

2. We point to the remarkable and innumerable achievements by means of animal experimentation in the past in advancing the knowledge of biological laws and devising methods of procedure for the cure of disease and for the prevention of suffering in human beings and lower animals. We emphasize the necessity of animal experimentation in continuing similar beneficent work in the future.

3. We are firmly opposed to cruelty to animals. We heartily support all humane efforts to prevent the wanton infliction of pain. The vast majority of experiments on animals need not be and, in fact, are not accompanied by any pain whatsoever. Under the regulations already in force, which reduce discomfort to the least possible amount and which require the decision of doubtful cases by the responsible laboratory director, the performance of those rare experiments which involve pain is, we believe, justifiable.

4. We regret the widespread lack of information regarding the aims, the achievements and the procedures of animal experimentation. We deplore the persistent misrepresentation of these aims, achievements and procedures by those who are opposed to this scientific method. We protest against the frequent denunciations of self-sacrificing, high-minded men of science who are devoting their lives to the welfare of mankind in efforts to solve the complicated problems of living beings and their diseases.

LONDON LETTER

(From Our Regular Correspondent)

London, Dec 20, 1913

The Health of Schoolchildren

The annual report for 1912 of the chief medical officer of the board of education has just been issued It contains an exhaustive account of the measures which are being taken throughout the country to safeguard the health of schoolchildren Uncleanliness still occupies a large share of the time and energy of the officers of the school medical service, but the returns show a decided and progressive improvement, and the grosser forms of uncleanliness are now rare as compared with the conditions that prevailed when medical inspection was instituted in 1908 There are about six million children in the public elementary schools About 10 per cent suffer from serious defects of vision Among the causes given are heredity, early eye strain, defective lighting, infectious diseases and neglect in obtaining early medical advice From 1 to 3 per cent suffer from defective hearing; from 1 to 3 per cent have suppurating ears, about 10 per cent have adenoids, inflamed tonsils or enlarged cervical lymph nodes requiring surgical treatment, 1 per cent have ringworm, 1 per cent suffer from tuberculosis of readily recognizable form, from 1 to 2 per cent have heart disease, from 30 to 40 per cent have unclean heads or bodies, and more than half the children are in need of dental treatment

In five directions school hygiene has undergone evolution. There has been a steady improvement in the routine work of medical inspection, and ancillary undertakings There is less "leakage," more following up and more accurate clinical examination Secondly, there is fuller differentiation of abnormal children and a tendency on the part of authorities to modify the school curriculum in their behalf. Much time and labor are now being devoted to mentally defective, tuberculous, stammering, and frail or retarded children Thirdly, there has been an enlargement of the conception of the sphere of influence of the school medical officers Education authorities are finding that though they have been appointed in the first place merely to inspect children, they may fill a very useful place in the educational system Fourthly, there has been a marked advance in respect of medical treatment both in quality and in quantity Lastly, the intimate relation between school hygiene and education is becoming recognized and its application understood The equipment of the school, the character of the teacher, the importance of physical exercise and manual work, the relation of the leaving child to the national insurance system, to industrial employment, to further education in secondary schools, and to its own home life, are now receiving attention Thus the school medical work and the issues arising therefrom are beginning to form an integral part of our educational system

Actinomycosis in Ox-Tongues Imported from Argentina

Dr W J Howarth, health officer of the city of London, and Dr H Williams, health officer of the port of London, have issued an interesting report on actinomycosis in ox tongues imported from Argentina These tongues arrive in a frozen condition at the rate of 10,000 per week About 5 per cent were found to be diseased The lymph nodes were more frequently affected than the blades of the tongue The lesions were fairly characteristic and the area involved by a single nodule varied in size from a pea to a five shilling piece The health officers conclude that actinomycosis is wide-spread in cattle in Argentina and that the supervision exercised to prevent the exportation of affected organs is inadequate As a large percentage of the affected tongues showed the disease in the lymph nodes alone, they recommend that these should be left attached to the tongue and not removed, as is sometimes done, when it is impossible to determine whether or not the tongue has come from an infected animal From a review of the literature of the subject they have come to the conclusion that the question of actinomycosis in cattle and even the prevalence of the disease in general have not been adequately investigated

Electricity and Radium in Agriculture

Mr T Thorne Butler has given an interesting lecture before the Royal Society of Arts on the application of electricity and radium in agriculture He said that a great deal of experimental work was going on now with radioactive material, which gave in some cases such remarkable results that radium must be taken into serious consideration from an agricultural point of view The residues resulting from radium extraction, which contained only a milligram or two of radium to the ton, and were at present regarded as of negligible value, were sufficiently active to produce marked effects on germination and greatly to increase the size of the plants and crops In some cases an increase of 300 and 400 per cent had been obtained The stimulating effects of a new type of combined high-frequency and positive electricity apparatus on young chickens was also described Not only was the loss of the very young birds during the first few days after hatching in incubators minimized, but the chickens grew at more than twice the normal rate, thus costing less than half the usual amount to grow

Scarcity of Physicians in South Africa

In a previous letter to The Journal it was pointed out that, whatever its defects, the national insurance act has greatly improved the financial position of physicians engaged in industrial practice, and that consequently there was a great falling off in the applicants for official appointments, even when advertised at greatly increased salaries The effect has not been confined to the United Kingdom but has spread to our nearest important colony, South Africa In an editorial article in the *South African Medical Record* it is pointed out that a short time ago when a minister of the government received a deputation from district surgeons asking for improved conditions of service his reply was that "every district surgeoncy is at once applied for by any number of doctors under the present conditions" Now the state of affairs is exactly the reverse The demand for physicians in South Africa is in excess of the supply, particularly outside the larger centers of population The government has the greatest difficulty in filling, even temporarily, junior appointments, despite increased remuneration Many of them have been advertised for months Moreover, the demand for the purchase of practices, except in exceptional cases, is practically nil This condition has been brought about by several causes The country has recovered from the war and there has been a general increase in the financial condition of the people and consequently in their capacity to pay a doctor In the Rand, one of the wealthiest places in the world, the advances are so great that there are unexampled facilities for a young physician without capital to jump after the slightest preliminary stage of a hospital resident or an assistant into an ample competence Thus men are attracted here from other parts of South Africa which are left bare There is the further factor that the improvement in industrial practice in Great Britain, referred to above, has to a great extent cut off the recruiting ground for South African physicians

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec 26, 1913

Complementary Medical Instruction

At its last session the superior commission on medical instruction framed a bill intended to organize a system of complementary medical instruction It is intended for students about to take their degrees, doctors desirous of keeping up with the progress of medical science and for foreign physicians and students It will include lectures, lessons and laboratory work Dr Le Gendre, a physician of the Lariboisière Hospital, suggests that much of the course be devoted to the study of social laws in relation to medicine School physicians and physicians whose practice is concerned with industrial accidents will obtain aid from such instruction The decree organizing this course will soon be submitted to the president of the republic

Compulsory Antityphoid Vaccination in the Army

Dr Léon Labbé who is a senator, recently proposed a bill to make antityphoid vaccination compulsory in the army The Senate on December 19 passed the bill, making it apply to the active army and applicable to the reserves by ministerial decree The bill was sent to the Chamber of Deputies, December 20, and there sent to the army committee, which will soon report It has already elicited severe criticism Dr L Granjux in the *Bulletin médical* has pointed out the inconvenience of compelling a soldier to submit to a vaccination which is not obligatory on other French citizens of the same age There are, indeed, precedents Formerly, vaccination and revaccination against small pox were compulsory in the army, while similar proceedings were optional for the civil population, but the law with regard to public hygiene removed this distinction between the civil and military population Compulsory antityphoid vaccination appears necessarily inoperative to Granjux. No one would ever dare to call before a court martial a soldier who had refused to be vaccinated against typhoid, and, in any case, he would be acquitted. If a soldier, who is in most cases a minor, were to produce a certificate from his father declaring that he was opposed to antityphoid vaccination on his son, what would be the situation of the army physician whose duty it was to vaccinate him? It seems, however, impossible to extend antityphoid vaccination to all branches of the army. Professor Vincent, indeed, has taken care to specify that vaccination should be performed only on healthy subjects. The successes which he has reported recently are due in part to this selection; and certainly his statistics would be less inviting if antityphoid vaccination should be practiced among all soldiers, for not only bad risks would be encountered, but also opposition. While optional antityphoid vaccination is gaining ground in the army constantly, it is to be feared that as soon as it becomes compulsory it will elicit opposition and hitherto unknown bad results. It is to be feared, moreover, that if antityphoid vaccination were made compulsory, the garrison cities where typhoid is endemic would regard such hygienic measures as purification of water and improvement of drainage as useless since the inhabitants were protected from the disease by vaccination. To make antityphoid vaccination compulsory in the army, in the opinion of Granjux, would risk the progress of *social and public hygiene in France.*

The Causes of Mortality in France

The director of public charities and hygiene has just handed in to the minister of the interior his report on the sanitary situation of France in 1911. The death-rate for this year was high in France as in other countries. The total number of deaths was about 775,088, an average of about 1,959 deaths per hundred thousand inhabitants and an increase of 70,318 over the figures of the previous year, which, however, were exceptionally low. The excess of deaths representing the difference between the two years was composed as follows, according to the age of the decedents:

From 0 to 1 year	30,172 deaths
From 1 to 19 years	7,061 deaths
From 20 to 39 years	3,951 deaths
From 40 to 59 years	2,724 deaths
From 60 years and over	26,410 deaths

The mortality in 1911, thus, was particularly large among infants and old persons. The principal cause of the infant mortality was enteritis due to the exceptional heat of the summer. Typhoid fever in 1911 increased, causing an excess of 1,324 deaths over the average of previous years. There were 5,283 deaths due to typhoid, or 133 per ten thousand inhabitants. The heat of the summer affecting the sources of drinking-water was one of the causes of the increase of typhoid. The place occupied by cancer in the annual total of deaths continues to increase regularly and disquietingly in France as elsewhere. Cancer in 1911 had more victims than all epidemic diseases put together (31,768 against 29,470). The tuberculosis situation is also disquieting. Tuberculosis causes one-eighth of the total of deaths especially among persons between 20 and 40 years of age. At these ages 44 out of 100 deaths are due to tuberculosis.

Jubilee of the French Society of Stomatology

The Société de stomatologie française, December 13, under the presidency of Professor Landouzy, dean of the Faculté de médecine de Paris, celebrated the twenty-fifth anniversary of its foundation.

Death of Dr. Louis Jullie

Dr. Louis Jullien, surgeon of the Maison de Saint-Lazare, has just died, aged 63, after a long and painful illness. His "Treatise on Venereal Diseases," which appeared about thirty years ago, was crowned by the Académie des Sciences, the Académie de médecine and the Faculté de médecine de Paris, and was translated into several foreign languages. When the first edition appeared and for a long time thereafter it was the best book on the subject.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec. 19, 1913.

Physicians and the Krankenkassen

The serious difficulty with the Krankenkassen under the new medical insurance legislation, when the present contracts expire January 1, shows some prospect of being settled. The medical departments of the German *universities have once* more made the attempt through three representatives of the Berlin faculty, Professors Kraus, Orth and Passow, to secure through the secretary of state for the interior, a higher interest of the government in the affairs of physicians than hitherto, and to urge the secretary to an attempt at reconciliation between the representatives of the medical profession and those of the insurance societies. A proposal for mediation was presented to-day by the government to the Leipsic League through the three university professors, and this proposal of the government will be taken up within a few hours by the management of the Leipsic League in order to determine its practicability. Without doubt concessions must be made by both sides in order to secure peace. I think there is no reason to doubt the readiness of the profession for this step, but it is doubtful whether the managers of the Leipsic League may not find the sacrifice which will be required of the medical profession too great. The next few days will decide the matter.

In comparison with this important matter, all the other information with regard to the approaching trouble, which has been received from various parts of Germany, is of minor importance. I will only mention as worthy of note that the Berlin Medical Society, the largest medical society in Germany, took the position the day before yesterday that the acceptance of a closed position as insurance physician is not *compatible with membership in the Berlin Medical Society.* According to this, a member who transgresses this resolution may be expelled from the society, which would discredit such a physician before the public. [The Leipsic League publishes weekly the list of "closed" positions, that is, those in which the insurance company offers terms altogether unfair and unworthy of the profession.]

Loan Offered for Purchase of Radium

A few days ago a conference took place in the department of the interior, under the presidency of the director of the Prussian Medical Bureau, of the representatives of numerous communes of greater Berlin, which was called at the request of Professor His, the director of the Radium Institute of the Charité. It was announced that certain insurance companies, the Landesversicherungsanstalten of Berlin and Brandenburg, had stated that they were ready to place at the disposal of the communes of greater Berlin a capital of $125,000 (500,000 marks), at a relatively low rate of interest, for the purchase of 2 grams of radio-active substances. The right is reserved to the communes participating to collect fees for radium treatment from patients who are able to pay. The representatives of the communes gave their consent, but the final decision naturally lies with the various communal corporations.

Small-Pox Research

The sum of $10,000 (50,000 marks) is to be appropriated by the Reichstag to the Imperial Health office for new investigations on small-pox, especially work on obtaining vaccine material from pure cultures according to the process published by Staff-Surgeon Fornet of this city. Other questions connected with small-pox are to be studied, such as the difference between the germ of human small-pox and that of vaccinia and of the small-pox of the horse and some other animals.

The Physicians of Germany in 1913

According to Professor Schwalbe's Medical Directory for Germany for 1914, the number of physicians in Germany in 1913 was 34,136. Compared with the population, 66,835,000, this gives 5.11 physicians per 10,000 inhabitants. About 100 physicians must be subtracted who practice at the health resorts in summer and other cities in winter, and therefore are reckoned twice. The number of physicians in Germany has increased since 1901 from a proportion of 4.92 to 5.11 per 10,000 inhabitants. In addition, there are 168 ship-surgeons and 163 physicians in the German colonies. About 500 physicians are lost to Germany annually through death and emigration. The number of licenses and the number of medical students is continually increasing. In 1916, 2,000 young physicians may be expected to enter the profession. The physicians are unusually numerous in the large cities, the proportion being 9.6 per 10,000 inhabitants in the large cities with a total of about 15,000,000 inhabitants as compared with 3.8 per 10,000 inhabitants in the rest of Germany with a total population of over 51,000,000. It is estimated that there are in greater Berlin 11.09 physicians per 10,000 inhabitants. Wiesbaden has 28 physicians per 10,000 inhabitants, while the town of Hamborn has only 2.3. The number of women practitioners is steadily increasing, there being 151 in 1912 *and 195 in 1913. They prefer to settle in the* large cities. A similar increase is observed in the number of specialists.

Deaths

Silas Weir Mitchell, eminent as [illegible] universally known as a writer of historica [illegible] ly with the times of the Revolutionary and [illegible] power in Philadelphia; honored for his attainments the world over; died at his home in Philadelphia, January 4, from influenza, aged within six weeks of 85.

He was born in Philadelphia, February 15, 1829, the son of Dr. John Kearsley and Matilda (Henry) Mitchell. His preliminary education was obtained in the grammar schools of Philadelphia and the University of Pennsylvania. He was obliged to leave the latter institution in his senior year on account of ill health. His medical course was taken at Jefferson Medical College, from which he graduated in the class of 1850. He at once commenced practicing in Philadelphia, devoting especial attention to physiologic subjects. In 1862 he entered the army as Assistant Surgeon of Volunteers and served until the end of the war, during this period doing valuable research work on gunshot wounds and the nervous disorders resulting therefrom.

Silas Weir Mitchell, 1829-1914

Early in his career his literary work commenced and the titles of his scientific articles alone number more than one hundred. About 1882, Dr. Mitchell entered on his career as a writer of fiction. Many of his works, such as, "In War Time," "Roland Blake" and "Westways," his latest production, dealt with the times of the Civil War, while the scene of "Hugh Wynne, Free Quaker" was set in Philadelphia during the Revolutionary War. In addition to these more ambitious works, Dr. Mitchell was a prolific writer of short stories, most of which dealt with some particular phase of neurology or neuropathic conditions. His writings, both scientific and imaginative, are fascinating; his style is polished, his diction finished.

Dr. Mitchell was a Fellow of the American Medical Association and Chairman of the Committee on Memorial to Medical Officers who died in the Civil War; a fellow and once president of the College of Physicians of Philadelphia; a member and president in 1908 of the American Neurological Association; a member of numerous scientific societies, both American and foreign; a trustee of the University of Pennsylvania and of the Carnegie Institute, Washington. He was the recipient of many honorary degrees from noted institutions. These include the honorary degree of Doctor of Medicine conferred on him by the University of Bologna and the degree of LL.D. conferred by Harvard University in 1886, by the University of Edinburgh in 1885, by Princeton University in 1896, by the University of Toronto in 1906 and by Jefferson Medical College in 1910.

Dr. Mitchell was the first to institute "the rest cure" for neurasthenia, which became a recognized and valuable method of treatment, and is known the world over by the name of its originator.

Despite his advanced age, Dr. Mitchell retained, almost to the last, his physical vigor, and to the last, his mental acumen and literary ability. His last published work, "Westways," which dealt with the Civil War and which appeared in 1913, shows no diminution of interest or flagging in the charm of his writing.

Alfred E. M. Purdy, M.D. College of Physicians and Surgeons, New York City, 1861; assistant surgeon of volunteers during the Civil War; from 1870 to 1880, surgeon and chief surgeon of the Metropolitan police of New York City; a member of the Medical Society of the State of New York and New York Academy of Medicine; one of the organizers and consulting surgeon of the Methodist Episcopal Hospital, Brooklyn; for many years editor of the *Medical Register;* died at his home in New York City, December 25, aged 75.

Thomas Edge Parke, M.D. University of Pennsylvania, Philadelphia, 1871; for five successive terms chief burgess of the borough of Downingtown, Pa.; a member of the Board of Health of Downingtown; president of the Dime Savings Bank at Chester County, and manager of the Chester County Hospital since its organization; died at his home in Downingtown, December 12, aged 62.

Frederick Gaston Kolb, M.D. Medico-Chirurgical College of Philadelphia, 1908; a native of Bahia, Brazil, and a specialist in bacteriology and pathology of Hamburg, Pa.; died at the home of his aunt in Welch, W. Va., about December 16, from heart disease, aged 28.

George W. Van Zandt, M.D. Rush Medical College, 1865; for several years a practitioner of Charlotte, Iowa, and later a banker of Chicago; died at his home in the latter city, December 21, aged 80.

Felipe Martinez, M.D. National Medical School, Mexico, 1870; surgeon in the Mexican Army for many years; died at his home in San Francisco, December 10, from myocarditis, aged 72.

Elijah Marion Heflin, M.D. Keokuk (Ia.) Medical College, 1892; of Calmar; a member of the Iowa State Medical Society; died in Grand Island, Neb., December 20, aged 51.

John Wesley Lanius, M.D. Missouri Medical College, St. Louis, 1869; of Palmyra, Mo.; died in the Levering Hospital, Hannibal, Mo., October 15, from arteriosclerosis, aged 71.

William James Kornegay, M.D. College of Physicians and Surgeons, Baltimore, 1893; died at his home in Mount Olive, N. C., Decembere 12, from cerebral hemorrhage, aged 47.

William H. Gowan, M.D. Detroit Medical College, 1875; proprietor of a sanatorium in Detroit; died at his home in that city, December 16, from heart disease, aged 59.

Thomas Judson Wright, M.D. George Washington University, Washington, D. C., 1870; Bellevue Hospital Medical College, 1871; of Churchland, Va.; died in St. Christopher's Hospital, Norfolk, Va., December 15, from complications resulting from a fracture of the hip, two weeks before, aged 68.

James Parker Stedman, M.D. Boston University, 1882; a member of the consulting staff of the Boston University Hospital and formerly president of the Brockton Medical Society and Massachusetts Surgical Society; died at his home in Brockton, December 24, aged 56.

Edward Wirt Lamoreaux, M.D. University of Michigan, Ann Arbor, 1879; for two years instructor in anatomy in his alma mater; died suddenly at his home in Battle Creek, from acute dilatation of the heart, December 18, aged 59.

George F. Parsons, M.D. College of Physicians and Surgeons, Chicago, 1886; for many years a practitioner of Chicago; died at the home of his daughter in Peoria, Ill., December 29, from cerebral hemorrhage.

Arthur Barnard Brown, M.D. Tulane University, New Orleans, 1901; a Fellow of the American Medical Association and secretary of the Louisiana State Board of Medical Examiners since 1910; vice-president in 1911 and president in 1912 of the National Federation of State Board Examiners; untiring in his work for the elevation of standards for admission to the practice of medicine; died at his home in New Orleans, December 19, as the result of a nervous breakdown, aged 34.

Edgar Doak Capps, M.D. College of Physicians and Surgeons, New York City, 1891; a Fellow of the American Medical Association; professor of diseases of the brain and nervous system in Fort Worth University; oculist, aurist, laryngologist and neurologist, and secretary and treasurer of the Protestant Private Sanitarium; formerly city physician of Forth Worth and one of the editors of the *Texas Medical News;* died suddenly at his home in Fort Worth, December 19, aged 46.

Jesse Franklin Frisbie, M.D. Harvard Medical School, 1861; a member of the Massachusetts Medical Society; a member of the city council of Newton in 1882 and for five years a member of the Newton Board of Health; from 1862 to 1865 acting assistant surgeon, U. S. N.; founder and once president of the Newton Natural History Society and a member of the staff of the Newton Hospital; died at his home, December 17, aged 75.

Paul Arthur Soelberg, M.D. College of Physicians and Surgeons, Chicago, 1910; a Fellow of the American Medical Association; a member of the resident staff of Wisconsin State Hospital, Mendota, Wis.; assistant superintendent of the Valmora Industrial Sanatorium, Watrous, N. Mex.; died at the home of his parents in Granite Falls, Minn., December 16, from exhaustion due to a suppurative appendicitis which was inoperable, aged 28.

Charles Sumner Little, M.D. Johns Hopkins University, Baltimore, Md., 1899; clinical lecturer on pathology and clinical medicine in the medical department of Purdue University; pathologist to the Indianapolis City Hospital and physician to the Day Nursery; for the last six years in charge of the S. W. Little Coal Companies' Mines at Petersburg, Ind.; died at his home in that place, December 13, from heart disease, aged 40.

Edgar Martindale Hermance, M.D. College of Physicians and Surgeons, New York City, 1878; a member of the Medical Society of the State of New York; first commissioner of public safety of Yonkers; a member of the Board of Education and president of the Board of Health; consulting physician to St. Joseph's Hospital; died at his home, December 22, from pneumonia, aged 59.

Michael A. Jordon, M.D. Eclectic Medical Institute, Cincinnati, 1878; Medical College of Ohio, Cincinnati, 1879; of Logansport, Ind.; a director in several banks of the city; coroner of Cass County from 1884 to 1888; died in Johns Hopkins Hospital, Baltimore, December 13, a day after an operation for malignant disease of the stomach, aged 58.

Francis Henry O'Connor, M.D. Long Island College Hospital, Brooklyn, 1898; a member of the Vermont State Medical Society and a member of the staff of the Brattleboro Memorial Hospital since its organization; local surgeon of the Boston and Maine Railroad; died suddenly at his home in Brattleboro, December 26, from angina pectoris, aged 44.

William H. Stearns, M.D. University of Southern California, Los Angeles, 1899; a member of the Board of Education in Los Angeles, from 1897 to 1898; a member of the staff of the Pacific Electric Railroad and chief medical examiner of the Prudential Life Insurance Company; died at his home, December 16, from pneumonia, aged 44.

Waller Morton Holladay, M.D. Hospital College of Medicine, Louisville, 1885; a Fellow of the American Medical Association; an alumnus of Hampton-Sidney College, Va., and for more than ten years college physician and supervisor for the Hampton district; died at his home in Hampton-Sidney, December 21, from nephritis, aged 49.

Bartholomew John Leahy, M.D. Rush Medical College, 1893; for several terms president of the Dixon-Dakota County (Neb.) Medical Society; died at his home in Jackson, December 17, from angina pectoris and chronic nephritis, aged 43.

Francis M. Pickens, M.D. Rush Medical College, 1870; one of the oldest practitioners of Winfield, Kan.; a veteran of the Civil War; died in his office in Winfield, December 17, from accidental gas asphyxiation, aged 72.

Hartwell Isaac Williams, M.D. University of Mobile, Ala., 1887; a member of the Medical Association of the State of Alabama, died at his home in Columbiana, December 21, from rheumatism, aged 60.

William Samuel Jennings, M.D. College of Physicians and Surgeons, Baltimore, 1885; a life-long resident of the Edisto section of Orangeburg County, S. C., and an esteemed practitioner of Cordova; died at the home of his brother in Orangeburg, December 7, from disease of the kidney, aged 55.

Thomas Alvin Edwards, M.D. University of Louisville (Ky.), 1881; formerly a member of the faculty of Beaumont Hospital Medical College, St. Louis, Mo.; for ten years an invalid as the result of paralysis; died at his home in St. Louis, December 22, from cerebral hemorrhage, aged 57.

Francis Aloysius McManus, M.D. College of Physicians and Surgeons, San Francisco, 1911; aged 35; formerly of Chico, Cal.; was found dead on the Southern Pacific tracks near Crockett, Cal., December 15, as the result of injuries received from being struck by a train.

William W. Kerlin, M.D. Pennsylvania Medical College, Gettysburg, 1857; surgeon of volunteers during the Civil War; formerly of Lena, Ill., and for the last thirty years a practitioner of Storm Lake, Iowa; died at his home, December 20, aged 79.

Marriages

George Bilton Lawson, M.D., Roanoke, Va., to Miss Julia Kern of Indianapolis, at her summer home, Kern Cliffe, Botetorte County, Va., December 25.

John Hanley O'Connell, M.D., Topeka, Kan., to Miss Evelyn Fiero of Dallas City, Ill., at Carthage, Ill., December 22.

Wilson Pendleton, M.D., Aberdeen, N. C., to Miss Myrtle Virginia Smith of Charlottesville, Va., December 20.

Herbert Gunn, M.D., Mill Valley, Cal., to Miss Eleanor Ammon of Newcastle, Cal., December 22.

Albert S. Steiner, M.D., to Mrs. Etta V. Houts, both of St. Louis, at Chicago, December 6.

Stanley M. Hall, M.D., Clarence, Mo., to Miss Louise Linville of Edina, Mo., December 22.

Ira Mason Smith, M.D., Newport, Va., to Miss Eloise Wyatt of Richmond, Va., recently.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SODIUM ACID PHOSPHATE ADMITTED TO NEW AND NONOFFICIAL REMEDIES

Report of the Council on Pharmacy and Chemistry

The report which appears below was adopted by the Council and its publication authorized. Having adopted the standards proposed by the Association's laboratory, sodium acid phosphate was admitted to New and Nonofficial Remedies and the description of it appears in the New and Nonofficial Remedies Department of this issue.

W. A. Puckner, Secretary.

A referee of the Council presented the following report by the American Medical Association's Chemical Laboratory of an examination of sodium acid phosphate as found on the market along with a description of the product giving tests and standards proposed for its control:

Laboratory Report

The researches of Hanzlik and Collins (*Arch. Int. Med.* 1913, xii, 578; The Journal A. M. A., Jan. 3, 1914, p. 43) have definitely established that the bactericidal action of hexamethylenamin is dependent on its decomposition into formaldehyd, that its value as a urinary disinfectant is dependent on and proportional to the acidity of the urine and that the administration of sodium acid phosphate with hexamethylenamin renders the urine acid. Hence it appears probable that the use of this salt in medicine will increase.

As previous experience has emphasized the unreliability of little used medicaments, the laboratory deemed it important that the market supply of this substance be studied in order that those who use it could take steps to obtain a reliable product for their prescriptions

While the widely used official sodium phosphate may be obtained of exceptional purity, an examination of the market supply of sodium acid phosphate shows that it is decidedly variable and much less pure although not seriously impure After consultation with manufacturers, to whom the laboratory at this time expresses its appreciation for the information given, and having in view the conditions surrounding the manufacture of little used drugs, the following standards for sodium acid phosphate are believed to be fair both to those who make it and to those who employ it in their practice·

Sodium acid phosphate should contain not less than 82 per cent of anhydrous sodium acid phosphate, should not contain more than 15 per cent of water of hydration, nor more than 1 per cent of hydrated sodium sulphate and should be reasonably free from arsenic and heavy metals

The examination included the products sold by Mallinckrodt Chemical Works, *Merck and Co*, *Powers Weightman Rosengarten Company* and E R Squibb and Sons

The product of the Mallinckrodt Chemical Works and that of the Powers Weightman Rosengarten Company conformed in all particulars to the proposed tests The salt sold under the Merck label lost about 21 5 per cent of its weight on drying and contained sodium acid phosphate equivalent to but about 76 per cent of the anhydrous salt In other particulars it conformed to the tests proposed The Squibb specimen evidently contained an appreciable proportion of secondary sodium phosphate In other particulars it conformed to the standards proposed

Based on these standards, a description of sodium acid phosphate is herewith submitted which would be suitable for insertion with New and Nonofficial Remedies, should the Council decide to give recognition to this salt

RECOMMENDATION OF THE REFEREE

Your referee commends the timely report of the Association's chemists He recommends that publication of this report be authorized, that the submitted description of sodium acid phosphate be admitted to New and Nonofficial Remedies, and that sodium acid phosphate, M C W, and sodium acid phosphate, P W R, be listed as non proprietary preparations which comply with the standards adopted

W. H HALE, QUACK AND JAIL BIRD

"Can you give me any information about one Dr William E Hale, who is at the head of many so called 'British Medical Institutes' in the United States and Mexico? I understand that he was in the Colorado penitentiary for two years and was arrested in New Orleans and jumped his bail, coming to Mexico"
A W PARSONS, M D,
Tampico, Mexico

From the advertisements which Dr Parsons sends, one of which we reproduce, there is little doubt that "Guillermo E Hale" is the notorious quack, William H Hale Hale claims to be a graduate of the American Eclectic College This was a fraudulent concern and has been out of existence for years From 1883 until 1891 Hale and one G W Van Vleck were running a diploma mill in Cincinnati—the "Medical University of Ohio" Diplomas were sold for from $10 to $500 apiece In 1891 Van Vleck, who was 'president," "dean" and "faculty" of this notorious fraud, was arrested and put on trial for felony Hale fled the state and went to Denver, where he posed as a Chinese physician, "Dr Gun Wa" While there he was indicted in the United States District Court for fraud After the indictment, Hale fled to England and operated a fraudulent catarrh and deafness cure He was indicted in Liverpool, England, tried and sentenced to eighteen months in the penitentiary—and served it

He returned to the United States after the expiration of his sentence, was arrested in New York under the Denver indictment, and was sentenced to serve eighteen months in the penitentiary—and served it After his release he seems to have gone to New York, for in 1895 he was indicted in connection with another man for grand larceny It seems that Hale and his partner in fraud convinced a victim that he was suffering from serious kidney disease which would soon cause madness or death unless he took Hale's "radium cure," for which $1,500 was asked Hale pleaded guilty to this indictment and served eight months in the penitentiary at Blackwell's Island, N Y

UN VISITANTE DISTINGUIDO

El Prof Dr Guillermo E Hale, Presidente del Instituto Médico Británido, vendrá a Tampico

Tenemos el gusto de poder informar a nuestros lectores que el Presidente del Instituto Médico Británico Profesor Guillermo E Hale que acaba de regresar de su viaje a Londres hará acompañado de su Secretario una visita profesional a la oficina que en esta ciudad y en la Calle de la Aurora No 24 tiene establecida dicho Instituto el próximo Miércoles y Jueves 26 y 27 de Noviembre

Durante esta visita el Profesor Hale tendrá gran placer en recibir a usted darle una consulta y hacerle un examen gratis además si tiene usted parientes amigos o vecinos que se sientan afectados de algun modo, llévelos con usted y serán bien recibidos por tan notable médico quien les obsequiará con un examen, en prueba de la gran simpatía que siente por los habitantes de esta gran ciudad

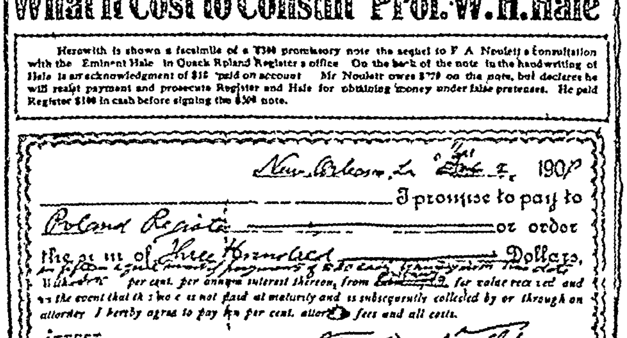
Fig 1—Photographic reproduction (reduced) of an advertisement in a Tampico Mexico paper of the British Medical Institute announcing the alleged visit of the distinguished "Professor" Hale This same swindle was worked extensively in the United States until the federal authorities put a stop to it

In 1900 Hale was in Jackson, Mich, where he was running what he called the "British Medical Institute" In the fall of 1902 he was arrested in Jackson for violating the medical practice act Through a technicality this case was non suited, but a warrant was sworn out within thirty minutes of Hale's release, in the mean time, however, Hale had fled This closed the "British Medical Institute"

From that time Hale seems to have been an itinerant His method was to make the rounds of various cities, his coming being advertised by local quacks, who sent letters to past and prospective victims These letters stated that "Professor" Hale or Doctor Hale, "one of the greatest living specialists in nervous, chronic and special diseases" is on a visit from London and will be pleased to see the patient in consultation with the man who sent out the letter The scheme was to obtain money



What It Cost to Consult "Prof. W. H. Hale"

Herewith is shown a facsimile of a $300 promissory note the sequel to F A Noulett's consultation with the Eminent Hale in Quack Roland Register's office On the back of the note in the handwriting of Hale is an acknowledgment of $15 paid on account Mr Noulett owes $270 on the note, but declares he will resist payment and prosecute Register and Hale for obtaining money under false pretenses. He paid Register $100 in cash before signing the $300 note.

New Orleans, La 1st 190
I promise to pay to
Roland Register or order
the sum of Three Hundred Dollars,
per cent. per annum interest thereon, from for value received and in the event that this note is not paid at maturity and is subsequently collected by or through an attorney I hereby agree to pay ten per cent. attorney's fees and all costs.
ATTEST
F. A. Noulett

Fig 2—Photographic reproduction from the New Orleans *Morning World* indicating what it cost one individual to consult "Professor Hale It will be noticed that the promissory note is made out to Dr Roland Register who *at that time* was acting as stalking horse for Hale

from these victims by this misrepresentation.[1] It seemed to be successful until it was tried in New Orleans. In this city the federal authorities got after Hale and his accomplices (A. S. Dyar and Roland Register) and in 1910 they were *found guilty, heavily fined and sentenced to the penitentiary.* Hale and his brother quacks appealed and the appellate court granted a new trial on the ground that the lower court erred in admitting the damning evidence against Hale.

Now it seems Hale is swindling the gullible in Mexico, and has resurrected his "British Medical Institute" and is now conducting the same fraud under the term, "Instituto Médico Británico."

Quackery is international in its scope. We trust that our southern neighbors will find it feasible to put "El Prof. Dr. Guillermo E. Hale Presidente del Instituto Médico Británico" where he can be kept at state expense. It will be much cheaper for the Mexican public.

Fig. 3—A greatly reduced reproduction of an advertisement of Roland Register An account of this man's arrest and conviction appears in "Nostrums and Quackery."

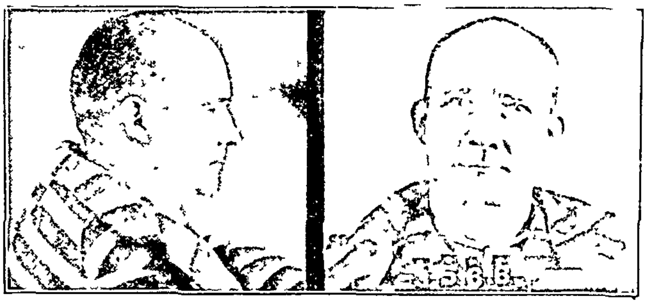

Fig. 4—William H. Hale—convict No 3566; from the records of the Illinois State Penitentiary at Joliet. At this time (1894-5) Hale was "serving time" as a United States prisoner from Colorado, for "using the United States mails under a fraudulent name in a scheme to defraud." In addition to the Bertillon record we find the following remarks regarding this prisoner: "Mole to the rear and top of right ear; small scar on right side of neck."

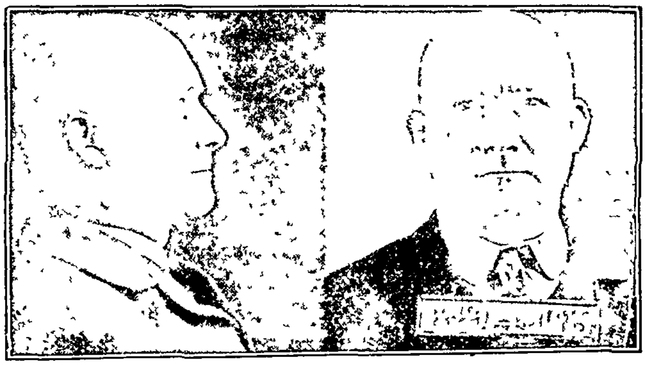

Fig. 5—William H. Hale as Convict K9415. Taken March 24, 1905, at the New York County Penitentiary, Blackwell's Island, N. Y. Hale is about ten years older in this picture than in the one taken at Joliet Penitentiary.

THE RICHIE MORPHIN CURE

In his series of articles on the "Great American Fraud" which ran a few years ago in *Collier's*, Mr. Samuel Hopkins Adams devoted one chapter to "The Scavengers." This appropriate title he applied to those scoundrels who, under the guise *of selling mail-order "cures" for the morphin habit,* fostered the slavery of the drug habit for their own profit by substituting for the morphin addiction an addiction to their villainous mixtures of opiates. One of the concerns described by Mr. Adams in this chapter was the Richie Company, Brooklyn, N. Y., of which he said:

> "Surrounded by the best religious influences, in the Presbyterian Building at 156 Fifth Avenue, New York City, the Rev. W. N. Richie, D.D., holds forth. Here, in pious words, he invokes the aid of Heaven upon his transactions. He has another address, 105 St. James Place, Brooklyn, where he does the work of Hell. By his catch-word, 'for the sake of humanity,' he has inveigled a numbe [illegible] *otherwise intelligent gentlemen into* [illegible] with their names. As high-minded a man as the late Rev. John Hall was duped, and his picture is now used on the cover of one of the Richie circulars. *Rev. Dr. Burrell,* the late Rev. S. S. Baldwin, Rev. C. A. Stoddard, and the editors of the *Independent, Christian Work* and other religious journals appear as endorsers of the Richie 'cure.' The 'literature' gotten out by the reverend exploiter reeks of a smug pseudopiety. He recommends his nostrum as a 'Painless cure for all drug habits. Only cure endorsed by the secretaries of Foreign Mission Boards, Interdenominational Committee, etc.' He claims that it will cause 'actual destruction of the desire for narcotics.' On his letter-head appear conspicuously the words, 'Supports better than the drug. No substitute.' Mark that 'No substitute.' This means that in the remedy no drug is substituted for the one used by the victim. It is a lie. The Rev. Dr. Richie knows it for a lie. So well does he know it that his employees dare not back it up in their correspondence. After procuring a sample of the output, I wrote, under an assumed name, saying that it produced the same effect as morphin, and asking if it contained any of that drug. Here is the reply: 'There would be no special advantage in our denying or asserting the use of morphin or opium in the remedy.' *'No special use,' indeed! Their sample, on analysis,* contains 2.12 grains of crystallized morphin per dose.
>
> "I am invited to *cure* myself by taking this stuff *four* times a day. If I lived through the first dose, the second would kill me, or any of my readers who is not a morphin fiend The ordinary dose is one-eighth of a grain, heavy dose one-fourth of a grain. But the Richie Company supposes I can stand more, so they endeavor to foist their concoction on me in place of my supposed addiction. How does this comport with their 'No substitution' claim? This and other questions I put in writing to the Rev. Dr. Richie. He has not answered it. His silence is not surprising. It is the part of wisdom—or, at least, caution. I'm not certain just how to place this reverend gentleman. It may be that he has been fooled into believing in the 'Richie cure,' and that he is an exemplar of a type of asininity so baneful and deadly that its possessor ought, for the sake of the public, to be permanently established in an asylum for the dangerously imbecile. But I think not. I think he cannot be ignorant of his traffic in ruined lives. This alternative implies flat criminality. Nor has the divinity doctor always eluded the clutch of the law. He has been convicted and fined for practicing medicine without a license."

The foregoing appeared in *Collier's* Sept. 22, 1906. On Jan. 5, 1909, June 5, 1909 and March 15, 1910, the Richie Company shipped from the state of New York into the District of Columbia three consignments of their villainous "cure." Samples from the different consignments were analyzed by the Bureau of Chemistry of the Department of Agriculture and the federal chemists reported that the product consisted of a watery-alcoholic solution of morphin sulphate, glycerin, pepsin, salicylic acid and undetermined matter. The first shipment consisted of five bottles which contained morphin sulphate in amounts varying from 14.2 grains to the fluidounce to 9.2 grains to the fluidounce. The ten bottles in the second shipment contained this same drug in amounts varying from 12.35 grains to 7.21 grains to the fluidounce. The third shipment of ten bottles also contained morphin sulphate, varying in amounts from 15.85 to 8.22 grains to the fluidounce.

---

[1] The scheme is fully described in THE JOURNAL'S article on "Hale, Dyar and Register," that appeared Oct. 15, 1910, and has been reprinted in the second edition of "Nostrums and Quackery."

On March 14, 1911, more than two years after the first shipment was made, the United States Attorney for the Eastern District of New York, acting on the report of the Secretary of Agriculture, filed an information against William N. Richie and Grant N. Richie, who were copartners under the name "Richie Company." The product was declared misbranded because the bottles and packages did not bear a statement on the label of the quantity and proportion of morphin.

On March 18, 1911, the two Richies entered a plea of "not guilty" and three months later filed a demurrer. The court overruled the demurrer and on April 2, 1913, William N. Richie and Grant N. Richie withdrew their former plea of "not guilty" and entered a plea of "guilty."

And what punishment was meted out to these two men, who were engaged in a business compared with which housebreaking and bankwrecking are respectable? None at all! The court suspended sentence.—(*Notice of Judgment No. 2554, issued Oct. 31, 1913.*)

Hard to Believe

P. D. & Co.'s monologist was in the editorial office the other day chanting the Phylacogen Magnificat, "Praise it and magnify it forever." In the course of his eulogy he stated that a correct diagnosis is essential to the successful use of Phylacogen and that in the practice of those physicians who have reported their cases to P. D. there have been but 2 per cent. of failures. We believe that it is within the bounds of cosmic possibilities that there may exist a remedy so remarkably efficient that it will cure all but 2 per cent. of cases. It is true that none of our highly prized specifics have been so efficacious even in fields far more restricted than that assigned to Phylacogen; still it is possible to conceive of such a remedy. When, however, we contemplate physicians making 98 per cent. correct diagnoses we feel that we are in view of what Kipling calls "The True Romance." We have at times believed in Dr. Cook, Reform Politics and the Pittsburgh Pirates, but when we tried to conceive of diagnosers with a batting average of 98 per cent., our editorial believer stripped its gears.—*The Mirror*, the official organ of the Fayette County (Pennsylvania) Medical Society.

Correspondence

The Better Control of Ophthalmia Neonatorum

To the Editor:—A recent communication on this subject in The Journal (Dec. 13, 1913, p. 2177) criticizes the proposed gratuitous distribution of a prophylactic for the prevention of ophthalmia neonatorum as recommended by the Committee on the Prevention of Blindness of the Council on Health and Public Instruction. The writer of the communication, Dr. Stotter of Cleveland, thinks that undue restrictions are placed on the midwife as compared with the physician. A careful reading of this bill as it appears in The Journal for June 21, 1913, p. 2004, will show that the responsibility for reporting the existence of a birth infection of the eyes of a new-born infant is placed impartially on the responsible person in charge, whether physician, midwife, nurse, relative or whomsoever may have been in charge of the mother and child. As Dr. Stotter has evidently misunderstood the purport of the bill, it is not unlikely that others who have not given the matter careful consideration may fail to understand the reasons for each of its suggested provisions, and as these were reached only after careful consideration and extended conference with ophthalmologists, obstetricians, sanitarians and others, a brief explanation concerning them may be helpful in securing the judicious criticism which it is desired to elicit. It will be remembered that the bill is purely tentative and is published as a basis only for future legislation. While criticism is invited, therefore, it should be on the provisions actually found in the bill and not on those which it is supposed to contain.

After the essential features of the bill were determined on it was finally submitted to counsel employed by the American Medical Association in order that the phraseology might be conformable to law.

The title was found to be a matter of first importance and must embody the substance of the bill, as otherwise the validity of the law itself might be attacked.

In order to avoid ambiguity a definition of ophthalmia neonatorum was found to be necessary. Cases which had been brought to trial in Massachusetts were contested for the reason that the infecting micro-organism in these cases was not the gonococcus, and it was claimed that the resultant inflammation did not constitute ophthalmia neonatorum. If it were always insisted on that a microscopic examination be made to determine the nature of the disease, no conviction could be obtained, for if only the gonococcic cases were reported the stigma which this would carry would make it impossible to secure any reports whatever. To require this examination as a preliminary to each report would be most undesirable, moreover, and to limit ophthalmia neonatorum to those cases of gonococcic origin would be unscientific and unwarranted by the facts, for it is not only the gonococcic cases that are the serious ones. While the large majority of other infections do not result in loss of sight, the pneumococcus, the Klebs-Löffler bacillus and other organisms which are occasionally present are often equally dangerous. It is wise to emphasize the fact that many cases are innocent. When all cases are brought promptly to the attention of the department of public health it makes possible the securing of immediate treatment for those which urgently require it, whatever may be their origin.

The responsibility does not rest entirely on the attendant at the birth of a child. The health boards have many duties, and that of protecting the eyes of the new-born is one. It must be exacted, therefore, that the officer in charge of the department of health shall take such action as will secure the report in order that he may be enabled when necessary to take the proper steps to obtain for the child when infected prompt and adequate treatment. This is equally true of the state department of public health. Rules and regulations must be promulgated for the needs of the local health officers, and it must be made easy to use a prophylactic on the part of the physician by having it placed in his hands together with advice as to the manner in which it should be used and the necessity for its employment.

It is necessary periodically to print and publish such advice and information "lest we forget." After a peculiarly disastrous case an obstetrician will usually for a long time be careful in his procedures and in his use of a prophylactic. This is by no means always so. Cases have been brought to the knowledge of the Commission for the Blind in Massachusetts in which within a comparatively short time a second child has become infected in the same family and the second child has become blind. But even if the physician in charge never has another infected case he will have added his quota to the blind man's world and the lesson will have been lost.

We all need constant reminders. This is the special value of having placed on the birth-report the inquiries, "Have you used a prophylactic? If not, why?" An answer to these questions may not legally be insisted on, and an enforced answer cannot be secured. The obstetrician may decline to answer if he chooses, but whenever he makes the report of a birth the danger of birth infections to the eyes of the infant will be impressed on his mind, and the wisdom of using a prophylactic at least in all suitable cases will be emphasized; but if he fails to answer these questions or if his answer is in the negative without adequate reason and the child shall have become infected and in consequence blind, it is presumptive evidence that an important safeguard has been omitted and would seriously prejudice the interests of the physician in the event of a suit for malpractice being instituted. For his own protection, therefore, it is wise not only that he should use a prophylactic but also that he should report having done so. The obstetrician is justified in a case in which he is morally certain that there can be no possibility of infection in omitting the use of a silver salt in the child's eyes, but in the light of the fact that the irritation which follows is so simple and the protection in a large number of cases so great there is no doubt whatever that a majority of obstetricians prefer its routine employment It is especially desirable when it is given gratuitously that it should be of an absolutely standard strength—that it should be put up in light proof ampules which are air tight, and from which the solution cannot evaporate—which is easily carried, inexpensive, and which can be used without danger of injuring the eye of the infant Such ampules are now put up by the health department of the state of New York, and last year more than 17,000 of the outfits together with literature in English, German, Italian and Polish were distributed advising midwives and others of the dangers of birth infections to the sight, the necessity of using prophylaxis, and of reporting cases to the board of health

The reason for the gratuitous distribution of the prophylactic is not to save cost to the obstetrician, as the expense in any event is trifling, but in the first place to prevent accidents, as cases have been known in which errors on the part of the physician in writing the prescription, or the pharmacist in putting it up, have resulted in securing a preparation of dangerous strength—or because through the effect of light the solution has lost all protective value—or because, as often happens, in time of necessity the obstetrician finds that the cork has been lost from the bottle and that it is dry, and therefore is not used—or because the bottle is not in the satchel—or because in an ordinary bottle it becomes easily infected and is no longer clean, because the dropper is not clean—because, for a dozen other reasons, the simplest and safest solution to be used is the standard preparation which is issued at little cost from the laboratory of the health department F Park Lewis, M D, Buffalo, N Y

[A proof of the foregoing was submitted to Dr Stotter, who replies]

To the Editor —While thoroughly in sympathy with all that is being done by my esteemed colleague, Dr F Park Lewis of Buffalo, for the better control of ophthalmia neonatorum, I beg to insist that I have not, as is suggested, misunderstood the purpose of the tentative bill heretofore published, in claiming that undue restrictions are placed on the midwife as compared with the physician A careful reading of this bill (Section VI) shows that while a money fine is imposed on all persons responsible for failing to report the existence of infection, the ultimate punishment provided for the midwife is revocation of her license No such or similar punishment is provided for the physician Should not the physician, much better qualified than the midwife, pay the forfeit for any such neglect—"lest we forget?"

In Volume XX of *Transactions of the American Association of Obstetricians and Gynecologists*, Dr Lewis refers to two essential factors in the prevention of blindness first, more enlightenment, a broader, more general, popular knowledge of the causes and the measures to be employed, and second, perfectly organized and coordinated effort in securing its control He quotes the distinguished Cuban, Dr Santos Fernandez, as saying, "The important thing is to bring before the public mind by means of constant propaganda, a knowledge of the danger to a recently born child at all affected as to the eyes and to call the attention of the family to the facilities which the authorities will furnish them to guard against blindness" (As a matter of fact, *do* our local associations favor *full* publicity in this matter?)

To this I would add such other means as public lectures, and the distribution of printed instructions to those who consult our free dispensaries and clinics, without making any secret of the unfortunate truth with its due consequences I recall a saying by Fuchs of Vienna to a delegation that called to intercede for a medical student who had failed in his question in chief—the chemical and physiologic action of silver salts in ophthalmia of the newly born "I might overlook a wrong diagnosis of glaucoma," said Dr. Fuchs, "and any mistake you propose for the treatment of a diseased eye, but you would be unworthy of your high calling were you to lose a single eye from ophthalmia neonatorum"

James Stotter, M D, Cleveland

Antiquity of the Patent-Medicine Plague

To the Editor.—To show the antiquity of the patent medicine plague I beg to call your attention to the following extract from a letter of Sylvester Graham, written at Providence, March 6, 1834, and published in the *Graham Journal of Health and Longevity*, Boston, 1837, i, 116

"'Stop! Stop! sir!' says the mercenary vendor of specifics and patent medicines, 'look at the wonders which have been performed by the Panacea, the Catholicon, the Hygeian Medicine, etc, etc See the long list of certificates in the newspapers!' Yes, I see them, and my heart aches for suffering and outraged humanity! Go ask the graveyards for their certificates! Were there a tongue to tell the secrets of the 'narrow house,' the ears of the specific mongers would tingle with a revelation infinitely more horrible than that which the ghost of Hamlet's father dared not to tell to ears of flesh and blood I know that in the thousands and thousands of cases where these specifics are used, it sometimes happens that an individual is apparently benefited by them, but for this one instance hundreds and thousands are hurried to the grave The single apparent cure is trumpeted to the world, but the grave in everlasting silence swallows up its hecatombs of human sacrifices It may be thought that I express myself too strongly on this subject; but the sufferings and devastation which I have seen resulting from these all pervading scourges of the world, wake up the fervent sympathies of my soul and constrain me to speak out . The paltry jargon of these books and advertisements of Hygeian Medicine about the 'impurity of the blood' etc, etc is a tissue of the most arrant misrepresentation falsehood and humbugging that ever deceived mankind" Graham Lusk, New York

Testimonial-Giving Seventy-Five Years Ago

To the Editor —That the attitude of the medical profession toward patent medicines and panaceas has changed for the better in the last three quarters of a century is evidenced by the following, quoted in the *Medico Chirurgical Review* (London, England) for October, 1836, preceded by these words from the editor "We were utterly astonished to find an impudent PANACEA bolstered up with the names and certificates of some of the first authorities in the medical profession of the United States! We were thunderstruck on perusing such documents as the following

'From Doctor N Chapman, *Professor of the Institutes and Practice of Physics and Clinical Practice in the University of Pennsylvania, President of the Academy of Medicine, Philadelphia, etc*

' 'I have within the last two years had an opportunity of seeing several cases of inveterate ulcers, which having resisted previously the regular modes of treatment, were healed by the use of Swain's PANACEA, and I do believe, from what I have seen, that it will prove an important remedy in scrofulous, venereal and mercurial diseases

"'N Chapman, M D'

"From Doctor W Gibson, *Professor of Surgery in the University of Pennsylvania, Surgeon and Clinical Lecturer to the Almshouse, Infirmary, etc*

"'I have employed the PANACEA of Mr Swain, in numerous instances within the last three years, and have always found it extremely efficacious, especially in secondary syphilis and in mercurial disease I have no hesitation in pronouncing it a medicine of inestimable value

"'W Gibson, M D'

"From Doctor Valentine Mott, *Professor of Surgery in the University of New York, Surgeon to the New York Hospital, etc*

"'I have repeatedly used Swain's PANACEA, both in the Hospital and in private practice, and have always found it to be a valuable medicine in chronic, syphilitic and scrofulous complaints, and in obstinate cutaneous affections

"'Valentine Mott, M D'

"From Doctor William P. Dewees, *Adjunct Professor of Midwifery in the University of Pennsylvania, etc.*

"'I have much pleasure in saying I have witnessed the most decided and happy effects in several instances of inveterate disease from Mr. Swain's PANACEA, where other remedies had failed—one that of Mrs. Brown.

"'Wm. P. Dewees, M.D.'"

It goes without saying that these men were in the very forefront of the medical profession in America three-quarters of a century ago, and this fact evoked the following closing paragraph from the editor of the *Medico-Chirurgical Review:*

"*Eheu jam satis!* We are mortified and grieved, beyond measure, to find professional propriety (to give it no other name) at so low an ebb among our brethren in America! This admonition from Europe will surely rouse the faculty of the United States to some sense of the duty they owe to their brethren throughout the world."

CHARLES B. JOHNSON, M.D., Champaign, Ill.

[COMMENT: Times change and we change with them! In 1836 British physicians were astounded at the spectacle of American medical men giving testimonials for nostrums. In 1914 American medical men view with astonishment and dismay the tendency on the part of European physicians, British and Continental, to laud proprietary remedies of the most evidently fraudulent type. Testimonial-giving by physicians in the United States is practically a thing of the past; in Great Britain and on the Continent it is so common as to arouse no comment.—ED.]

Imported Medication and Dr. Stelwagon's Formula

To the Editor:—Apropos of the remarks on "Imported Medication" in the Therapeutics Department (THE JOURNAL, Dec. 13, 1913, p. 2159), it may prove of interest to your readers to compare the prescription headed "A Formula for Combined Stomachic and Laxative Effects," with a startlingly similar prescription given in "Essentials of Diseases of the Skin," by Henry W. Stelwagon, M.D., Ph.D., clinical professor of dermatology in the Jefferson Medical College (Philadelphia, W. B. Saunders Company, 1900, p. 118). In the paragraph describing the constitutional treatment when indicated in acne the author states that "in dyspepsia and constipation, bitter tonics, alkalies, acids, pepsin, saline and vegetable laxatives are variously prescribed. Special mention may be made of the following:

"℞	Ext. rhamni pursh. fl.	fʒ ii ʒiv
	Tinct. nucis vom.	fʒ iii
	Elix. calisayae, q. s. ad	f℥ iii

M. Sig.: ʒi t. i. d."

Compare this with the formula which you state was "copied verbatin from the *Paris médical*":

℞	Fluidextracti rhamni purshianae,	ʒ v	(20 grammes)
	Tincture nucis vomicae,	ʒ ss	(2 grammes)
	Aquae laurocerasi,		
	Syrupi,	āā ℥ ss	(15 grammes)
	Aquae destillatae,	℥ iii	(100 grammes)

M. Sig.: Three or four teaspoonfuls daily.

In other words, one of our leading dermatologists was recommending practically the same formula not less than thirteen years *ago. So much for the "newness" of the prescription*, as far as its really active ingredients are concerned, namely, the cascara and nux vomica.

Dr. Stelwagon's mixture is not exactly pleasant to take, and the suggestion you make about giving cascara and nux vomica separately is a good one. Still, many patients, in my experience, do not find the mixture much, if at all, more unpleasant to take than the separately administered drugs, preferring one bitter dose to two or three less bitter ones.

Since 1903, first in general medical work and later in eye, ear, nose and throat practice, I have used this formula for the indications outlined by Dr. Stelwagon, with extremely gratifying results, its bitter taste to the contrary notwithstanding. In many patients, particularly women, referred for examination of eyes and nose to find possible cause of headache, I have found those organs normal. Many such patients were complaining of constipation, poor but not markedly upset digestion, and more or less anorexia, but other more definite symptoms were not elicited by their physician or myself. Such patients almost invariably were relieved of their headaches by Dr. Stelwagon's formula, or the later and possibly worse-tasting one I used in Panama, in which the compound tincture of cinchona was substituted for the elixir of calisaya.

RICHARD M. NELSON, M.D., Atlanta, Ga.

Blood Transfusion in 1666

To the Editor:—In reading the celebrated diary of Samuel Pepys I recently came across the first account, so far as I know, of the transfusion of blood, which I think will be of interest to the readers of THE JOURNAL. The following is an extract:

"Nov. the 14th, 1666. Dr. Croone told me that at the meeting at Gresham College to-night (which, it seems, they now have every Wednesday again), there was a pretty experiment of the blood of one dog let out (till he died) into the body of another on one side, while all his own run out on the other side. The first died upon the place, and the other very well, and likely to do well. This did give occasion to many pretty wishes, as of the blood of a Quaker to be let into an Archbishop, and such like; but, as Dr. Croone says, may, if it takes, be of mighty use to man's health, for the amendment of bad blood by borrowing from a better body.

"Nov. 16th. This noon I met with Mr. Hooke, and he tells me the dog which was filled with another dog's blood, at the College the other day, is very well,and like to be so as ever, and doubts not its being found of great use to men; and so do Dr. Whistler, who dined with us at the tavern."

MICHAEL CAMPBELL, M.D., Bearden, Tenn.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RESPONSIBILITY OF SURGEON IN USE OF ROENTGEN RAY

To the Editor:—There are two legal questions affecting the rights and the interests of the surgeon, concerning which I should like to ask for information.

A. Is there any opinion holding a surgeon responsible for not using the Roentgen ray in fractures and other surgical conditions in which the Roentgen ray might be an aid to diagnosis? Would this be affected by the inability of the patient to pay the expenses that would have to be incurred?

B. First, is there any opinion holding the surgeon responsible when he tells the patient in advance that the result, under the *conditions of the treatment, will not be satisfactory* and yet treats the patient with the result foretold? Secondly, if a surgeon treats a patient because of the inability of the patient to pay hospital expenses or surgeon's fees under unfavorable conditions as to attendance and environment, etc., is he responsible for the result, if not satisfactory? The second question partly covers this.

R. D. O.

ANSWER.—The fundamental consideration underlying these questions is, What is the measure of a physician's duty and liability in diagnosing and treating a supposed fracture or a supposed surgical condition of any nature?

In the treatment of any particular case a physician must use such reasonable skill and diligence in applying or administering any medicine or means used as would be exercised by the average physician of the same community under similar circumstances (*Spain v. Burch* (Mo.), 154 S.W. 172; *McGraw v. Kerr* (Colo.), 128 Pac. 870; *McBride v. Huckins* (N.H.), 81 Atl. 528; *Sawyer v. Berthold* (Minn.), 134 N.W. 120; *Robinson v. Crothwell* (Ala.), 57 So. 23; *Mosslander v. Armstrong* (Nebr.), 134 N.W. 967; *Hinkle v. Smith* (Ga.), 77 S.C. 650; *Osborn v. Carey* (Idaho), 132 N.W. 967; *Booth v. Andrews* (Neb.), 137 N.W. 884).

A.—Is a physician bound to use the Roentgen ray in diagnosis? Would the liability of the physician be affected in any way by the fact that the failure to use the Roentgen ray was owing to an inability on the part of the patient to meet the expense thereof?

1. The failure to use the Roentgen ray as a means of diagnosis may, under all the facts, be a mere mistake of error or

judgment for which a physician is not generally liable (*McGraw v. Kerr* (Colo.), 128 Pac. 870; *Taylor v. Kidd* (Wash.), 129 Pac. 406).

2. A patient is always entitled to a thorough examination by his physician such as an ordinary and skilful physician would give under the circumstances (*Rogers v. Kee* (Mich.), 137 N.W. 260; *Sawyers v. Berthold* (Minn.), 134 N.W. 120).

3. Yet a failure to use the Roentgen ray would not necessarily be an error so gross as to be inconsistent with that degree of skill which it is the duty of a physician to possess and exercise, irrespective of any fee which may enter into the case (*McGraw v. Kerr* (Colo.), 128 Pac. 870; *Rogers v. Kee* (Mich.), 137 N.W. 260; *Sawyer v. Berthold* (Minn.), 134 N.W. 120; *Taylor v. Kidd* (Wash.), 129 Pac. 406; *McBride v. Huckins* (N.H.), 81 Atl. 528).

4. The skilfulness of a physician in diagnosis and treatment should be tested by the recognized rules of his own school and must be determined by resort to the testimony and opinion of experts, not only as to whether the defendant exercised ordinary care and skill in examining the case but in applying the remedies as well, and such an opinion is to be based on all the facts of the case (*McGraw v. Kerr* (Colo.), 128 Pac. 870; *Taylor v. Kidd* (Wash.), 129 Pac. 406; *Rogers v. Kee* (Mich.), 137 N.W. 260.

5. It would seem essential for evidence to be adduced that under the given conditions and all the facts it is usual and customary at the particular time and place and among physicians of the defendant's school, or immediately necessary, to use the Roentgen ray in diagnosis, or thereby to prove that failure so to do constitutes want of care and skill, taking into consideration the fact that the patient could not afford to use the Roentgen ray and that he was fully advised under the circumstances (*McGraw v. Kerr* (Colo.), 128 Pac. 870; *Rogers v. Kee* (Mich.), 137 N.W. 260).

6. Under the rule above stated the burden will rest with the patient to prove that it is usual and customary for the average physician in the correspondent's city in the exercise of ordinary skill and care to insist on the use of the Roentgen ray in diagnosing a case despite the fact that the patient is unable to pay therefor and taking into due consideration all the other facts that may enter into any given case; otherwise no liability attaches to the physician.

B.—Is a surgeon liable for unsatisfactory results due to treatment under unfavorable circumstances as to attendance and environment owing to the patient's inability to pay hospital expenses, etc., supposing the surgeon has warned the patient in advance as to the probable results?

1. Physicians and surgeons do not impliedly warrant the recovery of a patient and are not liable on account of any failure in that respect, generally speaking, unless through some default of their own (*Booth v. Andrews* (Neb.), 137 N.W. 884).

2. In an action for damages against a licensed physician the presumption is that he has performed his duty to his patient and also that the physician has correctly prescribed for and treated the patient. If the contrary be alleged the burden is on the patient to establish any liability on the part of the physician (*Booth v. Andrews* (Neb.), 137 N.W. 884; *Cozine v. Moore* (Iowa), 141 N.W. 424; *Hinkle v. Smith* (Ga.), 77 S.E. 650; *James v. Robertson* (Utah), 117 Pac. 1068; *Ballard v. Railway* (Ky.), 139 S.W. 771; *Bigger v. Railway* (Mo.), 140 S.W. 602; *Hales v. Raines* (Mo.), 141 S.W. 917; *Frazin v. Ins. Co.* (Mo.), 141 S.W. 936; *Fields v. Traction Co.* (Minn.), 133 N.W. 577).

3. Hence the burden would again rest on the patient to prove that under all the circumstances the physician had failed to exercise that ordinary degree of skill and care that is exercised by physicians in his locality; otherwise no liability attaches to the physician.

Under both A and B the issue raised would most properly be left to the jury to decide as to whether or not the physician had exercised the proper degree of skill and care. If this be decided in the affirmative, then as a matter of law there is no liability. If in the negative liability would attach, and it would be incumbent on the jury to affix damages.

LITERATURE ON THE BINET TESTS FOR ESTIMATING MENTALITY

To the Editor:—Please publish a bibliography concerning the Binet tests for estimating mentality.

R. P. Stoops, M.D., Crosbyton, Tex.

Answer.—Following are references to the recent literature:

EPINEPHRIN IN PRESCRIPTION

To the Editor:—Some months ago, having learned that the Council on Pharmacy and Chemistry of the A. M. A. had adopted epinephrin as a generic term for all adrenal preparations, I gave up prescribing adrenalin chlorid, and have since ordered epinephrin. I have had difficulty in getting a prescription filled at times, the pharmacist stating that he did not have that particular preparation in stock.

In the Practical Medicine Series, viii, 111, Butler states that epinephrin is a trade-marked name. Is this true, and if so, how should my prescriptions be written to permit the pharmacist to dispense any one of the adrenal preparations?

Linn Emerson, M.D., Orange, N. J.

Answer.—Epinephrin is a non-proprietary unprotected name, originally used by Professor Abel, and adopted by the Council on Pharmacy and Chemistry to designate the active agent of the suprarenal glands. When used in a prescription, especially if followed by the designation N. N. R., the druggist ought to understand that any one of the preparations mentioned in N. N. R. can be used to fill the prescription.

GARDNER'S AMMONIUM HYPOPHOSPHITE AND HYPO-QUINIDOL

To the Editor:—I enclose herewith R. W. Gardner's booklet on Ammonium Hypophosphite and Hypo-Quinidol and would be pleased if you would give a report of them in The Journal.

S. V. Romig, M.D., Chicago.

Answer.—Gardner's Syrup of Ammonium Hypophosphite is a syrup containing 3.33 gm. ammonium hypophosphite in each 100 c.c. (16 grains in each fluidounce). It has the properties of ammonium hypophosphite. Both ammonium hypophosphite and Gardner's Syrup of Ammonium Hypophosphite are described in New and Nonofficial Remedies, 1913. An exammation of the advertising matter both of the circular sent in and of that which is in our files fails to show that R W Gardner makes any definite statement in regard to the nature or the composition of his Hypo Quinidol Certain statements made in the literature sound much as if the article might be some sort of a quinin hypophosphite preparation But if this is true, its action would be the same as other salts of quinin and the extravagant claims made could not be substantiated It is said to be a "non toxic quinin" It is safe to say that a quinin which will not produce the toxic symptoms—cinchonism—either is not absorbed in sufficient quantity or has been so changed that it no longer has the therapeutic properties of quinin Altogether Hypo Quinidol must be put down as a preparation the composition of which is kept secret and regarding which extravagant and highly improbable statements are made

DOES THE JOURNAL NEGLECT THE EAST?

To the Editor —The enclosed speaks for itself If it is of value to the profession use it although I prefer my name to be kept out of it Most of the frauds you have uncovered worked the West I do not remember an Eastern or New England concern that you have shown up since I became a subscriber

X———, Massachusetts

Answer —Our correspondent enclosed in his letter some material sent out by the Neal Institute This concern was discussed in The Journal, April 5, 1913, under the title, "The Gatlin Institute"

That we have not neglected the east in our propaganda work will be evident from the following partial list of products or concerns that have been exposed in The Journal since November, 1912 — the time at which our correspondent became a subscriber

Faget's Hair Tonic, Baltimore, Nov 16 1912
Duffy s Malt Whiskey Rochester N Y Nov 23 1912
Peeke s Epilepsy Cure New York City Nov 30 1912
Baume s Analgesic Balm New York City Dec 14 1912

Dowd s Phosphatometer, Buffalo, Dec 20, 1913

WORKS OF NAPOLEON S SURGEON GENERAL

To the Editor —Can you inform me if there is an English translation of the works of the surgeon general of Napoleon I, and if so, where it can be obtained?

F H Stibbens, M D, San Francisco

Answer —The following are works of Dominique Jean Larrey, surgeon in chief of the French army during the Napoleonic campaigns

Memoirs of Military Surgery of French Army on the Rhine, in Corsica, etc Baltimore 1814, J Cushing
Observations on Wounds, Philadelphia Mielke & Biddle, 1832
Surgical Memoirs of Campaigns of Russia, Germany and France, Philadelphia, Carey & Lea, 1832

These books are now out of print, but copies can probably be picked up second hand

TREATMENT OF PERSPIRING FEET

To the Editor —1 What is the best treatment of perspiring feet?

2 Has any author devoted special attention to this?

P L S

Answer —1 The cautious use of the Roentgen ray is recommended as the best method of checking excessive perspiration Among the local applications which may be used with benefit are tannic acid, alum or zinc sulphate in from 1 to 8 per cent solutions (from 1 dram to 1 ounce to a pint of water) Another useful application is a 1 per cent dilution of liquor formaldehydi in water The parts should be washed and then bathed in one of these solutions for several minutes twice daily and afterward powdered with boric acid with or without 1 or 2 per cent salicylic acid

2 We know of no special work on this subject It is treated in the works on diseases of the skin

Medical Economics

This Department Embodies the Subjects of Post Graduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

A NEW MEDICAL ORGANIZATION IN ENGLAND

The discussion and bitter feeling engendered by the passage and enforcement of the British national insurance act has culminated in the organization in England of a new national body known as the National Medical Union This organization grew out of the conference of delegates representing the so called "non panel practitioners," that is, the physicians of England who have for various reasons declined to go on the "panel" or list of physicians available in each locality for services under the insurance act Commenting on this new organization, the *Medical Press and Circular*, an independent journal of London, says that as far as can be gathered from the published reports, the reason for the organization appears to be opposition to the insurance acts themselves and opposition to the management of the British Medical Association As was noted at the time, the special representative meeting of the British Medical Association held shortly after the passage of the insurance act took a radical position against the provisions of the act and called on the individual members of the association to pledge themselves not to take part in the enforcement of the act When the test came up, however, and the individual physicians were called on to decide whether they would place their names on the list of physicians available under the law, or enter a protest by refusing to take part in enforcing its provisions, a large majority of the members of the association enrolled themselves as eligible for local services Those physicians who adhered to their pledge have consequently been dissatisfied with the present situation The peculiar condition which at present exists is that the new organization, which is practically called into existence through dissatisfaction with the British Medical Association, is made up largely of members of the association who have conformed to the policy of the association itself

The new organization seems to find a great deal of difficulty in determining the qualification for membership It was first proposed to accept only physicians not concerned in any way in service under the insurance act A wide difference of opinion prevailed, but a compromise was finally effected by the adoption of a rather vague resolution providing that membership should be limited to those not on the "panel," leaving the determination of individual cases to local organizations Commenting on this point, the *Press and Circular* says, "The National Union starts on an apparently contradictory constitution that indirectly admits panel men to a non panel organization" Regarding the general situation, the *Press and Circular* is equally emphatic It says that there is little doubt that the machinery of administration and the management of the British Medical Association leave much to be desired, and that, at any rate, there is room for another medical organization to undertake important functions either neglected or inadequately performed by the British Medical Association as now conducted The new organization starts out with about a thousand members and fifty local associations The number of non panel physicians in the United Kingdom eligible to membership is estimated at about ten thousand but after deducting consultants and specialists and those holding official positions who are consequently not affected by the new act the total number of active non panel practitioners to which such an organization would appeal would be about five thousand

RECENT DEVELOPMENTS IN GERMANY

In Germany, the government has taken a hand in the effort to carry out the provisions of the industrial insurance laws in force in that country The ministers of trade, agriculture and the interior have issued a general order, outlining methods to be followed by insurance societies which may fail to secure a sufficient number of physicians by January 1. This order authorizes insurance societies, in case they are unable, through no fault of their own, to furnish medical services, to pay their insured persons a lump sum of money in place of furnishing professional services. This action is regarded as unfavorable to the position which the physicians interested have taken. The Federation of German Doctors Unions has issued a statement calling attention to the fact that the present struggle is not against individual members of the insurance societies, but is only against the management of these societies, and that physicians throughout Germany will continue to take care of their individual patients, as individuals, but not as members of the insurance societies. The so-called strike of physicians is, therefore, not against the patients but against the organizations. The statement contains detailed directions to individual physicians as to what action is to be taken under existing circumstances. Physicians are directed to charge exactly the same fees that they would receive if they were doing the work for the insurance societies. The *British Medical Journal*, commenting on the German situation, says that if the profession is strong enough and sufficiently united to carry out the fight in the manner indicated in the instructions of the executive committee, a complete victory for the physicians is sure to be the result. As the lack of unity among the members of the British Medical Association was the important and determining factor in the British situation, it will be interesting to know whether the German profession is any more united and will stand together better than did their professional brethren in Great Britain.

PRESENT STATUS OF OPTOMETRY LEGISLATION

A number of inquiries have been received regarding optometry laws. From the most recent and best available information, it would appear that optometry laws have been adopted by twenty-eight states as follows:

1901—Minnesota.

1903—California and North Dakota.

1905—Oregon.

1906—New Mexico.

1907—Arizona, Idaho, Indiana, Montana, Nebraska, Tennessee and Utah.

1909—Delaware, Florida, Iowa, Kansas, Maine, Michigan, New York, North Carolina, Rhode Island, Vermont, Washington and West Virginia.

1911—New Hampshire and Oklahoma.

1913—Nevada.

A diagram of optometry legislation would show that this movement had its inception in the early part of the last decade. It gathered its impetus throughout this period, and apparently reached its high-water mark about 1909. From 1910 to the close of the legislative year 1912-1913 only four states adopted such laws.

During the latter period optometry bills have been introduced in the different legislatures and rejected as follows:

1910—Rejected in Kentucky, Maryland, Massachusetts, New Jersey and Ohio. Successful in none.

1911—Rejected in eighteen states. Successful in two states.

1912—Successful in one state.

1913—Rejected in Colorado, Connecticut, Missouri, New Jersey, Ohio, Pennsylvania, South Carolina, South Dakota, Texas and Wisconsin. Successful in one state.

At present there are twenty states in which the optometrists have failed to secure affirmative action for their bills, as follows: Alabama, Arkansas, Colorado, Connecticut, Georgia, Illinois, Kentucky, Louisiana, Maryland, Mississippi, Missouri, New Jersey, Ohio, Pennsylvania, South Carolina, South Dakota, Texas, Virginia, Wisconsin and Wyoming.

Vaccine Therapy.—The fundamental principle of vaccine therapy as I conceive it is to exploit in the interest of the infected tissues the unexercised immunizing capacities of the uninfected tissues.—Sir Almroth E. Wright.

COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 13. Chairman, Dr. W. H. Sanders, Montgomery.

ILLINOIS: The Coliseum Annex, Wabash Ave. and 16th St., Chicago, Jan. 14-16. Acting Sec., Amos Sawyer, Springfield.

INDIANA: Room 56 State House, Indianapolis, Jan. 13-15. Sec., Dr. Wm. T. Gott, 56 State House, Indianapolis.

KANSAS: Topeka, Feb. 9-11. Sec., Dr. H. A. Dykes, Lebanon.

MISSOURI: Jefferson Hotel, St. Louis, Feb. 9-11. Sec., Dr. J. A. B. Adcock, Jefferson City.

NEBRASKA: Lincoln, Feb. 11. Sec., Dr. H. B. Cummins, Seward.

NEW MEXICO: Santa Fe, Jan. 12. Sec., Dr. W. E. Kaser, East Las Vegas.

NEW YORK: Jan. 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Albany.

OKLAHOMA: Oklahoma City, Jan. 13. Sec., Dr. John W. Duke, Guthrie, Okla.

SOUTH DAKOTA: Capitol Bldg., Pierre, Jan. 13. Sec., Dr. Park B. Jenkins, Waubay.

VERMONT: Montpelier, Jan. 13-15. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: Spokane, January 6-12. Sec., Dr. F. P. Witter, Traders' Block, Spokane.

WISCONSIN: Madison, Jan. 13. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

"Quality, Not Quantity, in Medical Training"

Several times recently we have taken pleasure in noting the insight into medical matters shown by the Boston *Herald*. In its issue of Dec. 22, 1913, under the preceding heading, it said:

"Fifty-odd medical schools have gone out of existence in the last few years—either by actual cessation or by merger with other institutions, following the agitation for higher standards in medical teaching.

"The change is significant. By far too many schools were mere 'diploma factories,' with but a pretense at instruction. Preparation for the state board examinations was the curriculum. Other institutions, more sincere in purpose, were wretchedly inadequate, without proper laboratory and clinical facilities. The graduates from such schools entered practice doubly handicapped. They were usually unable to secure a hospital appointment and thus were obliged to treat with only the barest theoretical training.

"The effect on the medical profession has been marked. In many outlying districts, in particular, ignorant practitioners have brought the science into disrepute, driving their ill-treated patients either to out-and-out quacks or to cults of one kind or other.

"The evolution which has greatly lessened the number of 'medicos' should be beneficial in many ways. The profession has become greatly overcrowded—as have many other fields, to be sure. But keenness of competition is apt to be most disastrous in medicine, by tempting to departure from ethical standards and by unduly emphasizing the financial aspects of service. Wherever the physician's bread and butter becomes as important a consideration as his patient's welfare, the practice of medicine is marked for decline.

"For that reason the elimination of the cheap medical school—of the institution where payment for the whole course in advance is taken at a great discount—is gratifying. It will result in a better standardization of medical theory and practice, and in a continuance of the high plane of ethics on which the success of the profession depends."

Oklahoma July Report

Dr. John W. Duke, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Guthrie, July 8-9, 1913. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 70. The total number of candidates examined was 35, of whom 34 passed and 1 failed. Twenty-three candidates were licensed through reciprocity, including 2 osteopaths. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
University of Arkansas	(1913)	76
Bennett Medical College	(1913)	81
Chicago College of Medicine and Surgery	(1912) (1913)	88; 84, 90.
Rush Medical College	(1913)	87

Kansas Medical College	(1913)	84
Tulane University	(1913)	84, 85
St. Louis University	(1911)	77
University Medical College, Kansas City	(1913)	85

Memphis Hospital Med. Coll.	(1901) (1910)	Arkansas Mississippi
University of Nashville	(1901)	Arkansas
Meharry Medical College	(1910)	Tennessee

The following questions were asked:

ANATOMY

1. Describe the abdominal aorta. Give beginning, course and ending. 2. Give size, shape, origin and insertion of the pectoralis major muscle. 3. Give number of bones composing the pelvis. 4. Give articulations of the ethmoid bone. 5. Describe the difference between the intercostal nerves and the other spinal nerves, as to distribution. Give number. 6. What is transmitted through the foramen magnum? 7. Give number and name of the coats of the large intestine. 8. Give names of the ligaments of the liver. 9. Give the number of pairs of the spinal nerves. Name them. 10. Give the articulations of the humerus.

PHYSIOLOGY

1. Define: (a) function, (b) metabolism, (c) anastomosis, (d) endosmosis, (e) karyokinesis. 2. What do you understand calcification to be? 3. Describe the capillary circulation. What force propels the blood through the tissues? 4. What is the distribution of the anterior division of the 5th pair of spinal nerves including their connection with the sympathetic nervous system? 5. Give the chemical and physical properties of normal urine. 6. What part of the brain has supervision of the equilibrium of the body? 7. Give name of the first pair of cranial nerves, also their origin and function. 8. What are the functions of the kidney? 9. What is meant by a ductless gland? Name one and give its function. What nerves supply the muscles of expression?

CHEMISTRY

1. What is an element? What element is in all acids? What elements enter into formation of all organic bodies? 2. Complete the equation, $C_2H_5Cl+KOH=$What? After completing the equation name the compounds on either side of the equation. 3. How would you determine chemically whether a urinary deposit were composed of urates or phosphates? 4. Define the following: Allotropism, endosmosis, alloy, amalgam. 5. Give chemical antidotes for poisoning from apomorphin. 6. Give chemical antidotes for iodin and also formaldehyd. 7. Give chemical name and formula for iodoform. 8. What is an alkaloid? What is the difference between a base, salt and an acid? 9. If the specific gravity of a patient's urine were 1.014, would you make a Fehling's test of the urine? Outline the procedure for examination of urine for applicant for $1,000 life insurance. 10. Describe hydrochloric acid as to its occurrence. Give symbols for hydrochloric acid and antidotes (chemically) in case of poisoning.

PHYSICAL DIAGNOSIS

1. Define physical diagnosis. 2. How many methods of eliciting physical signs? Name them. 3. Name the most important of the methods. 4. Describe palpation. 5. What is auscultatory percussion? 6. Diagnose spasmodic asthma. 7. What do the methods of physical examination of the heart include? 8. What is a râle? 9. Define a murmur. 10. What is the rhythm of a murmur?

BACTERIOLOGY AND PATHOLOGY

1. Define bacteriology. 2. Describe a culture of typhoid bacillus. 3. What is a pyogenic microbe? 4. Name three microbes and classify them. 5. What is a spirillum? 6. Define pathology. 7. Give pathology of lobar pneumonia. 8. Give pathology of erysipelas. 9. Give pathology of diphtheria. 10. Give pathology of trachoma.

TOXICOLOGY AND MEDICAL JURISPRUDENCE

1. Give maximum dose of hyoscine hydrobromate. How would you treat a case of hyoscine poisoning? 2. What is the smallest fatal dose of white arsenic? Give shortest interval before death. Give treatment for arsenical poisoning. 3. What is the fatal dose of carbolic acid taken internally? How soon does death occur after the poison has been swallowed? Give treatment. 4. Give fatal dose of ergot. How would you treat a case of poisoning from the drug? 5. Give fatal dose of podophyllum. 6. What is general paresis? 7. What would be your method of examining a person suspected of feigning insanity? 8. If you were called on to help determine the plea of legitimacy, or to ascertain whether or not the woman had actually been pregnant, or if an attempt had been made to conceal a birth, how would you proceed to make the examination? 9. How would you go about having an insane person committed to the Hospital for the Insane in this state? 10. How would you differentiate between real concussion of the brain, and feigned concussion of the brain?

SURGERY

1. What is inflammation? How does inflammation extend and how may it terminate? 2. Make a differential diagnosis of coma from injury, apoplexy, uremia, opium poisoning and alcoholic intoxication. 3. With what conditions may aneurysm be confounded? 4. What are the methods of controlling hemorrhage? 5. What are the causes of secondary hemorrhage? 6. Describe resection of the knee-joint. 7. How would you perform tracheotomy? 8. Describe the operation for empyema. 9. When is operative interference advisable in the treatment of malignant tumors? 10. Give causes and treatment of rupture of the urinary bladder.

GYNECOLOGY

1. What are the physical signs of prolapsed ovary? Give treatment. 2 Describe the technic of catheterization. 3. Discuss ventrofixation of the uterus 4. Define vicarious menstruation? 5. Diagnose carcinoma of the breast. 6. Describe the malformations of the uterus. 7. Give causes of menorrhagia. 8. Describe the varieties of uterine fibroma. With what other conditions may they be confounded? 9. What is salpingitis? Give etiology. 10. What is a pessary? Give indications for its use.

OBSTETRICS AND HYGIENE

1. Give origin of blood and nerve supply of the uterus. 2. (a) Make a diagnosis of pregnancy at the twelfth week. (b) Can you make a positive diagnosis at this time? 3. Make a diagnosis of tubal pregnancy before rupture of the tube. 4. What conditions may simulate rupture of the tube in tubal pregnancy? 5. (a) How should the cord be dressed? (b) How would you control hemorrhage of the cord? 6. Treat a case of threatened abortion. 7. (a) What is the perineal body? (b) What are its functions? 8. (a) What are the signs of fetal death in utero? (b) Give treatment of a case. 9. What disposition would you make of the excreta of a typhoid patient? 10. What four diseases are more apt to be carried in milk?

MATERIA MEDICA AND PRACTICE

1. In what diseases may hemorrhage from the bowels occur? 2. Differentiate neuritis from neuralgia. 3. What is the difference between anesthetics and anodynes? 4. Define pertussis, dysphagia, uremia, kyphosis, hemoptysis. 5. Name the official digestive ferments and give indications for their use. 6. Give etiology, symptoms and treatment of erysipelas. 7. Give indications for the use of ergot. What is the effect of a toxic dose? 8. Discuss palpitation of the heart. 9. Compare the physiological action of belladonna and hyoscyamus. 10. For what is potassium permanganate used?

Connecticut November Report

Dr. Charles A. Tuttle, secretary of the Connecticut State Medical Examining Board, reports the written examination held at New Haven, Nov. 11, 1913. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 53, of whom 29 passed and 24 failed. The following colleges were represented:

Book Notices

Diseases of Women. A Clinical Guide to Their Diagnosis and Treatment. By George Ernest Herman, M.B., F.R.C.P., F.R.C.S., Consulting Obstetric Physician to the London Hospital. Assisted by R. Drummond Maxwell, M.D., F.R.C.S., Assistant Obstetric Physician to the London Hospital. Fourth Edition. Cloth. Price, $7.50 net. Pp. 899, with 300 illustrations. New York: Funk & Wagnalls Company, 1913.

For many years this was one of the most authoritative of British text-books on diseases of women. In its early form the work showed considerable variation from the conventional text. The author's original aim, as frankly set forth, was to provide a book which should guide the student and practitioner to the diagnosis and right treatment of the diseases of women. Without regard to anatomic classification he endeavored to present the different affections in the way in which they appeared in practice. Thus the work was classified according to symptoms, a scheme which has some definite advantage from a purely clinical point of view, if confusing to the reader accustomed to the commoner anatomic arrangement. After a few introductory chapters, chronic pelvic pain is discussed, then pelvic inflammation, and next internal hemorrhage in general and is followed by five short chapters on leukorrhea. The disorders of menstruation and of the sexual functions come next, followed by urinary and rectal complications. The volume concludes with a complete presentation of the subject of abdominal tumors. This arrangement is continued in the new edition, diagnosis and treatment again being emphasized. The greatest change in the present volume is in the parts relating to operative technic, the portion of the work revised by Dr. Maxwell. In the plastic work of cervix and vagina and in radical extirpation for malignancy, as well as in many other instances, the revision has added greatly to the book as a text. Many of the illustrations, including eight in color, are new.

Diseases of Women. Medical and Surgical Gynecology. By Charles A. L. Reed, A.M., F.C.S., M.D., Professor in the University of Cincinnati. Cloth. Price, $6. Pp. 944, with 448 illustrations. New York: D. Appleton & Co., 1913.

In this latest addition to the long list of American text-books on gynecology the writer has succeeded in his attempt to make a book that is at once systematic, direct and brief without being synoptic, and is comprehensive without being discursive. The author's clear, incisive style and talent for rhetorical presentation has enabled him to cover the wide range of subjects and present his views clearly and forcefully. He has presumed a knowledge by the reader of the elementary anatomy and pathology of the subjects treated. These, as well as the usual bibliographic tables, are therefore omitted. The genito-urinary diseases of women, surgical conditions of the kidney and ureter, surgery of the rectum and certain obstetric operations are included. The somewhat unusual arrangement of the matter which is carried out to its logical conclusion, aids materially in the use of the book for ready reference. It is divided into sections on malformations, injuries, displacements, foreign bodies, infections, neoplasms and trophic changes. Within each section the affection is considered generally in its relation to the anatomic regions, a chapter being devoted to each region.

We turn with particular interest to the section on infections. The gonococcus infection is treated at length, but we are somewhat disappointed to find no reference to the use of vaccines in diagnosis and treatment, a subject which really originated in this country. It would seem also that the important and special features of vulvovaginitis in children demand mention. Under streptococcus infection of the uterus the author considers puerperal infection and advises radical treatment that is opposed to the teaching of most obstetricians in this country. On the first sign of abnormal temperature, with or without chill, a careful exploration of the uterus is advised. If the symptoms are of intra-uterine origin, thorough curettement is advised. In the technic of curettage it is directed after the use of the curet and irrigation to pack the uterine cavity with gauze saturated with 98 per cent. phenol (carbolic acid), which should be left *in situ* from three to five minutes and then replaced for a similar length of time with gauze saturated with pure alcohol.

In the treatment of suppurating mastitis the author recommends that a drainage-tube should be inserted into the abscess and kept in as long as the discharge is purulent. In these cases many believe that the rubber drainage-tube often keeps open fistulas that would be avoided by the use of wick drains. No reference is made to the Roentgen and radium treatment of neoplasms. Section 8 is devoted to surgical conditions of pregnancy and parturition. Induction of abortion, ectopic pregnancy, rupture of the uterus, laceration of the cervix and perineum, symphyseotomy and cesarean section are considered. Just why these obstetric operations should be included and the others omitted is not apparent. The last section is devoted to menstruation and its diseases and was written by Dr. Dan Millikin for the "Text-Book of Gynecology," published in 1901. As it has not been revised it does not include the important changes in our knowledge of menstruation that have resulted from the epoch-making work of Hitschmann and Adler. The illustrations are nearly all original. While many are sketches and some more or less diagrammatic they are very satisfactory in giving a clear picture of what is intended. The book as a whole is an interesting and valuable contribution to our literature and a credit to its author.

Laboratory Methods in Agricultural Bacteriology. By F. Löhnis, Ph.D., Professor of Agricultural Bacteriology in the University of Leipsic. Translated by William Stevenson, B.Sc., N.D.A., N.D.D., Lecturer on Dairying to the West of Scotland Agricultural College, and J. Hunter Smith, B.Sc., N.D.A., N.D.D., Lecturer on Agricultural Chemistry and Bacteriology to the University College of South Wales and Monmouthshire. Cloth. Price, $1.75 net. Pp. 136, with 42 illustrations. Philadelphia: J. B. Lippincott Company, 1913.

This little manual is somewhat original. Undoubtedly the time is near when agricultural colleges will offer work in branches of agricultural bacteriology in addition to the courses offered at present in dairy bacteriology and soil bacteriology. The book gives directions for study of bacteria and their activities which are of special interest to agriculturists. The first part introduces the student to bacteriologic technic in general by useful experiments with air, water and foodstuffs. The bacteriology of milk naturally receives much attention. The work outlined includes study of the bacterial flora of milk, giving special attention to various forms of lactic acid bacteria. Methods of examination of butter and cheese are also given. In addition work on the bacteriology of manures and soils is outlined. On the whole the book is well arranged and the directions ample, but the English translation might be occasionally clearer and more concise. There are many useful illustrations fairly well reproduced.

The Microtomist's Vade-Mecum. A Hand-Book of the Methods of Microscopic Anatomy. By Arthur Bolles Lee. Seventh Edition. Cloth. Price $4 net. Pp. 526. Philadelphia: P. Blakiston's Son & Co., 1913.

The additions to this manual have been mostly in small details and yet have increased the index by more than 700 new entries. The staining of neurofibrils is so important in the author's opinion that the sections on this subject have been almost entirely rewritten. The same is true with sections dealing with the blood and blood parasites. Some matters of theoretical interest have been omitted so that the book is of a more convenient size.

A Practical Treatise on Medical Diagnosis. For Students and Physicians. By John H. Musser, M.D., LL.D. Sixth Edition. Revised by John H. Musser, Jr., B.S., M.D., Instructor in Medicine in the University of Pennsylvania. Cloth. Price, $5 net. Pp. 793, with 223 illustrations. Philadelphia: Lea & Febiger, 1913.

So rapidly has this subject grown and so frequent are the additions and changes, that a sixth edition of this valuable guide has been thought necessary. New sections have been added to the discussions on the disturbances of the internal secretions, and a new chapter has been added dealing with the various functional tests of organic efficiency. Other sections have been reviewed and much material abbreviated and condensed.

Miscellany

False Advertising

It is becoming increasingly evident that the enactment and fairly efficient enforcement of the national and state food and drugs laws has not secured to dealers and consumers freedom from fraud and deception in food and drug products.

False and misleading statements, designs and devices that appear in any other place than on the label attached to the package, or the false and deceptive methods used by designing agents, salesmen or manufacturers cannot be reached or prevented by resort to the food and drugs law and thus, in many instances, the public continues to suffer by reason of gross misrepresentation of one kind or another. Take, for illustration, the false, extravagant and, in their final effect, often harmful claims of many of the fake nostrums and appliances which appear in glaring advertisements in newspapers, circulars or pamphlets, or are given by word of mouth by an agent to a prospective customer: in such cases the food and drugs law is powerless to protect the purchaser.

An illustration of fraudulent advertising is that of the methods of a certain baking-powder company whose agents and demonstrators are instructed to make what is called "the water-glass tests." Several baking-powders are used, a small quantity of each being placed in a glass and water added. The baking-powder of this particular manufacturer contains a small quantity of albumin, and this powder containing the albumin foams to the top of the glass, the dissolved albumin making a more or less viscous liquid which retains the gas bubbles; the other powders which do not contain albumin simply foam up, the gas escaping into the air. The spectator sees the powder containing the albumin foam up to the top or over the top of the glass, while the other powders have but few bubbles; the opportunity is thus presented to the demonstrator or agent to represent to the housewife or prospective customer that the leavening power of the baking powder showing the glass full of bubbles is very much greater than that of the powders which do not make this showing, and thus a fraud is practiced in that the albumin powder is made to appear better than it really is, or conversely, that the other powders are made to appear worse than they really are. This test is deceptive, and is no indication of the raising power of the respective baking-powders. Such a demonstration is no test of strength; there is no reason why the consumer should pay more for baking-powder which foams and is retained in the glass because of the albumin content than he pays for powder of the same leavening power which contains no albumin and will, therefore, not foam and retain the bubbles when the water is added to it. The amount of albumin which is added to the baking-powder is only a fraction of 1 per cent., and its cost is negligible.

Patent medicines, food products and baking-powders should be sold for exactly what they are, and false representations of any kind are frauds on the purchaser. It is for these reasons that a false advertising law is imperatively necessary as a supplement to the food and drugs laws.—S. J. Crumbine, M.D., Secretary, Kansas State Board of Health.

Methods and Equipment in Milk Production

Rosenau in his book "The Milk Question" says that "clean milk may be produced with clean methods and poor equipment, but good milk cannot be produced with good equipment and poor methods." The truth of this statement is recognized by sanitarians, but experimental proof is scarce. Bulletin 365 of the New York Agricultural Experiment Station by Harding, Ruehle, Wilson and Smith shows that the authors have attacked this question and that they have brought to light some interesting facts. In certified milk dairies much time and labor is expended in washing and clipping cows and in keeping the interior of the stables in a scrupulously clean condition. The authors have obtained surprisingly low bacterial counts, in a large number of samples below 1,000 germs per cubic centimeter, without application of extreme precautions. If the number of bacteria is taken as index, the milk produced was of the highest quality. That milk of this quality is not generally produced under such conditions is illustrated by the fact that a local commercial dairy in which the equipment resembles that of the experiment station, except that steam is not available for treating utensils, quite uniformly turns out a product with a germ content of approximately 1 million germs per cubic centimeter. The difference between the two establishments is that at the experiment station the stable is kept cleaner, the cows are much cleaner, the milkers are clean and the utensils thoroughly steamed. One or more of these factors apparently contribute to bring about the difference in germ content.

The experiments were designed to test the influence of protected milk-pails, plastering or otherwise renovating the interior of the stable, clipping the cow's udder and flanks and cleaning the cows by hand or vacuum cleaner. The influence of protected pails was tested by covering two pails with cloth and leaving two pails uncovered, after having steamed the pails for fifteen minutes. While the milk from the covered pails averaged 922 germs per cubic centimeter, the milk from the uncovered pails averaged 2,391, an increase of 160 per cent.

In order to contrast the effect of old construction under unfavorable conditions with new construction at its best, the dust was allowed to accumulate on walls, ledges and stanchions until they were in as bad condition as would be tolerated under reasonably good barn management. Cows were milked under these conditions and after this study the ceiling and walls down to within 3 feet of the floor were covered with wire lath and two coats of cement. The last 3 feet were covered with zinc. Comparison of 212 samples showed that there was no measurable effect from the change of condition. Only after painting was there a decided reduction in number of germs.

The effect of clipping cows was tested next. The results show that clipping increased the probability of germs finding their way into the milk and no support is given to the idea that clipping the udder and flanks is a valuable aid in the production of sanitary milk. The authors think that brushing or otherwise cleaning the natural coat of the cow removes the loose dirt from the surface and other portion of the hair, while dirt at the base is retained. When the hair is clipped the cleaning process probably removes a larger proportion of dirt, but during the milking process there is little protective covering to retain dirt and bits of dead skin which are constantly breaking loose.

Comparison between cleaning cows with a brush and comb at the rate of two per minute with treatment with a vacuum cleaner at the rate of one per minute showed practically no difference in germ content.

The authors used all necessary precautions to have conditions for all experiments as nearly uniform as possible excepting in regard to the points to be determined.

The important fact which gradually is being recognized through these and other observations is that the production of clean milk with low germ-content is a simpler and less expensive process than has been believed, and it is desirable that the factors governing clean milk production should be better understood.

A Blackmailing Scheme

The following is from an editorial in the *Journal of the Indiana State Medical Association*, Nov. 15, 1913:

> Our attention has been called to what seems to be a blackmailing scheme worked on unsuspecting physicians. We have in our possession three letters, exactly alike as to composition, handwriting and substance, with each signed by a different name and mailed from a different Indiana town. The letter, less names and signatures, is as follows:
>
> .... 1913.
> Dr.....................................
> ....Indiana.
>
> Dear Doctor:
>
> You will no doubt be surprised to get this letter from a stranger, but oh, I am in such awful trouble that I must get help soon or I will go crazy.

I am in a family way, nearly two months gone, unmarried and deserted. That tells the whole miserable story in a few words.

I must get free at any cost, as I would much rather die than have it become known.

Won't you help me or tell me of some one you think would? If you will I will pay you well for it and be forever grateful to you for saving me from worse than death. Please do not be angry with me for asking your aid. I could not bring myself to go to one I know, and I heard a lady from here say you were a good doctor. I feel sure that if you knew all the circumstances and how much this means to me you would not condemn me.

I can make an excuse to get away for a short time and if you can assist me in any way please let me know at once how much it will cost me and how soon I can act.

Kindly use plain envelope
Sincerely yours,
Miss ....

We are informed that if the letter is answered, a young girl soon puts in an appearance, and no matter what attention is given her, her visit is followed some weeks later by the visit of a man who claims to be a relative of the girl, and who makes the statement that the girl has lost her life through the effects of an abortion, and that on her person was found the doctor's letter, professional card, etc. It is then made to appear that things look bad for the doctor, and that suit will be brought unless the matter can be settled out of court. Whether the doctor is guilty or not, he sometimes is weak enough to yield to the temptation to avoid notoriety, and pays the price that is asked for silence. The fact that several Indiana physicians have received the letter which we herewith reproduce, all of the letters being in the same handwriting, but sent from different towns and with different signatures, lends color to the supposition that a well-devised scheme of blackmail is on foot, and members of the medical profession should be on their guard.

[This would seem also to be a case for the postal authorities.—Ed.]

Surviving Superstitions among the Laity. — Physicians almost daily come across curious superstitions among their patients in regard to medical things which seem to belong to a less enlightened age. They are not always found among the ignorant and uneducated, but often among people of some education and otherwise fairly intelligent. The mental fog or obliquity signified may account in a measure for the vogue of cults and quacks. The *Weekly Bulletin* of the New York City Health Department sets forth some of these traditions and superstitions, racial, religious and otherwise, as encountered by the inspectors and nurses when urging parents to have various physical defects found among schoolchildren treated or corrected. When glasses are suggested for defective vision they are told that eye-glasses are a luxury, that they make the child look old, that they are worn for style, that the child will get used to them, that they will become a habit and the eyes will become weaker, or that they will interfere with the matrimonial chances of the daughter. Objection to the treatment of an ear that has a discharge may be based on the statement that the discharge allows the poison to escape and thus purifies the blood, or that at home the child hears too much anyway. If the parents are urged to have tonsils and adenoids removed it will be said that God put them there and if removed, the throat will be too wide, the air will rush into the lungs and cause inflammation; that the removal of the tonsils will interfere with speech, the singing voice or the procreative power, or that the children will become nervous and depressed, possibly with suicidal tendencies. Among the colored population voodooism is said to be frequent, for the attempt is made to cure diseases of the skin and eyes by the use of yarns of various colors. Suggestion that hair matted by dirt and lice be cut brings the protest that cutting the hair will prevent the growth and diminish the strength of the child. Pulling the teeth, it is said, will cause sore eyes; it is bad luck for any poor child to have gold or silver in the mouth. The "evil eye" is guarded against in some sections by the mother hastily licking the child's eyes and face, expectorating as she does so, or by sewing salt in the child's shirt, or tying red ribbon around the wrist or neck. Weakness of memory is attributed to eating the ends of the bread loaves, and bed-wetting is ascribed to playing with fire or matches before going to bed.

Suit for Malpractice Not Barred by Judgment in Justice Court for Services

(Barton vs. Southwick (Ill.), 101 N. E. R. 928)

The Supreme Court of Illinois holds that an action for malpractice is not barred by a judgment before a justice of the peace in favor of the physician, in an action brought by him for the services rendered the patient, when the defense of malpractice is not interposed thereto.

It was charged in this case that the defendant was negligent and guilty of malpractice, in that having been called as a physician to attend and prescribe for her while she was suffering from some disorder of the generative organs, which had resulted in what is commonly known as "flooding," he improperly and wrongfully diagnosed her case as one of pregnancy, informed her she was about to have a miscarriage, and proceeded, by the use of various instruments, to attempt to remove the fetus supposed to be present; that the plaintiff was not pregnant, and the defendant was so careless and negligent in the use of such instruments as to lacerate the uterus, thereby compelling the plaintiff to submit to a major surgical operation and suffer the removal of her uterus. The defense in the trial court on the facts was that the defendant employed proper treatment to stop the flooding, that he did not diagnose the case as one of pregnancy, and that he did not insert any instrument into the uterus or attempt by the use of instruments to remove a fetus. The plaintiff recovered a judgment for $2,300, which the appellate court reversed, without considering the merits of the case, because it considered the action barred by a judgment in favor of the physician in a suit subsequently brought by him in a justice's court. Now the Supreme Court reverses the judgment of the appellate court, remanding the cause, with directions to consider the case on its merits.

The Supreme Court says that the New York courts have held that a judgment against a patient, before a justice of the peace, in favor of a physician for his services, is a bar to the prosecution of a suit for malpractice against the physician by the patient, even though no defense of malpractice or any attempt to set off or recoup damages on that account was made at the trial. The courts of some other states have followed the New York cases, but the majority of other courts have only partially followed the New York courts.

This court held in *Howell vs. Goodrich, 69 Ill. 556*, that a judgment in favor of a physician before a justice of the peace, where the defendant appeared and interposed the defense of malpractice, was a bar to the prosecution of a suit against the physician for malpractice, and it would seem from the fact that a justice of the peace in Illinois has no jurisdiction to entertain an action for malpractice, a party having pending or contemplating bringing such a suit in a court having jurisdiction to try and determine it could not be compelled to defend the suit by the physician before the justice of the peace or be barred from prosecuting his suit for malpractice. The inconvenience, if not injustice, of requiring the party to defend against a judgment in the justice's court was referred to in *Resseguie vs. Byers, 52 Wis. 650*, where the court said: "If the plaintiff were compelled to make his defense in the justice's court that the professional services were of no value and that he had been injured by the defendant's negligence, then it would follow that he must either split up his demand, so that there might be two suits, instead of one, on it, or content himself with merely defeating the claim for services, or limit his damages to $200—the extent of the jurisdiction of the justice.

Responsibility on Surgeon Independent of Count of Nurses for Removal of Sponges

(Davis vs. Kerr (Pa.), 86 Atl. R. 1007)

The Supreme Court of Pennsylvania reverses a judgment rendered for the defendant and orders a new trial because it does not consider that it was a sufficient defense merely to show that he relied on a count of sponges made by a nurse The court says that the plaintiff had the defendant perform, at a public hospital, an operation on her for tuberculous peritonitis, when one of the sponges inserted, a piece of gauze about 12 inches in length, through somebody's mistake or negligence, was not removed, but was allowed to remain in the abdomen after the wound had been sewed up, and was not discovered until more than nine months following the operation, when a second operation was required for the removal of the sponge that had been overlooked In this case the defendant, preparatory to closing up the wound he had made, inquired of the nurses whether their count tallied, and whether all the sponges had been removed, and it was only on their replying affirmatively that he closed the wound The evidence would support no other conclusion than that the defendant was misled by the mistaken count of the nurses

Two questions were left to the jury to pass on: first, the credibility of the witnesses who testified that the defendant, before closing the wound, had inquired of the nurses whether all the sponges had been removed, and, second, whether the general system or practice of permitting the handling and counting of sponges by the nurses was reasonable The verdict of the jury was an affirmative finding as to each The court considers only the assignments of error relating to the rulings with respect to the second question

The rule of practice in hospitals to have one nurse take charge of a carefully counted supply of sponges and hand them to the operating surgeon as required, while it is the duty of another nurse to receive them from the operating surgeon after each has served its purpose, and have the nurses, when the operation has been concluded make comparison of those removed with those shown to have been introduced, required no submission to the jury That the precautions it required in order to avoid the serious mistake of allowing a sponge to remain in the abdomen after the wound had been closed were not only reasonable, but wise was not a subject of dispute A verdict of a jury was not needed to give sanction to a rule or practice in surgery adopted and approved so universally by those skilled in the science of surgery But, aside from this, however directly the negligence in this case might be traced to the nurses, the injury complained of could not be referred to the rule, but to the nurses' neglect in applying or observing the rule Therefore, as thus understood, the reasonableness of the rule was not a question in the case

The trial judge should have given the jury a very different understanding of what the reasonableness of the practice involved than that implied in his charge He instructed them "If you determine the custom was reasonable, or the practice, or whatever you choose to call it, custom or practice, among the surgeons, was reasonable, and Dr Kerr followed it then that is the end of the case, and you should return a verdict for the defendant Stop there and return a verdict for the defendant" There was here an unavoidable implication that involved in the rule, as an essential part of it, is exemption of the operating surgeon from liability in all cases in which, as here, the nurses report that their count shows a removal of all the sponges, and the wound is thereupon closed up with a sponge because of their mistaken count of the sponges Indeed, the whole case for the defendant was conducted on this theory, as appeared from the examination of the witnesses

The third point of the defendant was as follows "It being the undisputed evidence in the case that the counting of the sponges, both before and after an operation, was the duty of the nurses, and not of the operating surgeon, and it being further undisputed that the nurses reported to defendant, Dr Kerr, that all the sponges had been accounted for, the verdict of the jury must be for the defendant" The judge's answer was "That is affirmed, if you find that the practice or custom to have the nurses count the sponges is a reasonable and proper custom or practice" The instruction not only misconceived the purpose and object of the rule or practice but treated it as a rule defining the whole duty of the surgeon, limiting his responsibility accordingly Manifestly the only purpose in introducing the approved system or practice was to reduce as far as practicable the hazards to which the one operated on is exposed, by affording additional security against such accidents as here occurred It certainly did not contemplate that the security provided was to be the only security on which the patient could rely for the avoidance of such mishaps, displacing entirely those which had before been recognized, among these the skill and observation of the operating surgeon which had theretofore been employed and relied on to see that all the sponges had been removed It may well be that because of the additional security provided the burden theretofore resting on the surgeon was reduced, that whereas before it was his duty to take accurate count of the sponges, this duty being devolved on the attending nurses, the surgeon is enabled to give closer attention to the work immediately before him The court can well understand how better results can in this way be achieved But before the counting of the sponges by the nurses, and before the wound is closed, is it reasonable to suppose that no duty rests on the surgeon to employ his skill or observation to assure himself that no foreign substance has been allowed to remain within? This defendant did not understand the rule or practice as relieving him from all responsibility in this regard, for he testified that he supposed he had removed all the sponges and pads, and that, "when those were all removed, then my next step was to confirm that supposition by the statement of the nurse whose duty it is to count the sponges and to have her tally with the nurse who is handing the sponges to me, the clean sponges, or the ones that haven't been used" In making the observation which led him to conclude that he had removed all the sponges he was strictly in the line of his duty, and acting in accordance with the rules of the improved practice, according to his own testimony Granting the credibility of his testimony, the only question of fact remaining was Did he, in making his observation, exercise reasonable skill, care, and prudence? The surgeons who testified in behalf of the defendant united in saying that it is only in most exceptional cases, if any that the surgeon is warranted in exploring the restored parts after the count of the sponges by the nurses The court can understand how this is a reasonable rule of practice, but it does not concern the court here

The question related to what preceded the count by the nurses Here the surgeon had reached the conclusion that he had removed all the sponges, a mistaken conclusion, but verified by the nurses' count In reaching his conclusion, did he exercise ordinary skill? The court sees nothing in the evidence to warrant the inference that he did not, but, on the other hand, it finds nothing to warrant the inference that he did, which is far more important, since the burden of showing care was on him Why was a foreign substance left in the parts which the operating surgeon should have removed? It was for him to acquit himself of negligence with respect to it The sponge escaped his observation, why? Was it so hidden and concealed that reasonable care on his part would not have disclosed it, or were conditions such that in his professional judgment further exploration by him for sponges would have endangered the safety of the patient? In a word, did he do all that reasonable care and skill would require? Except as one or the other of these questions can be answered affirmatively from the evidence, the law will presume to the contrary, and attribute the unfortunate consequences to his contributing negligence For all that appeared in the case the retained sponge might readily have been discovered by the surgeon and reasonable prudence and care on his part would have avoided the accident If this were so, clearly his negligence contributed with that of the nurses and responsibility therefor in law attached

Diet —Every food determines a certain amount of digestive work, and when a given dietary is long continued, definite and fixed types of gland activity are set up which can be altered but slowly and with difficulty In consequence, digestive disturbances are often instituted, if a change be made suddenly from one dietary regimen to another, especially from a sparse to a rich diet —Pawlow

CHICAGO MEDICAL SOCIETY

Regular Meeting held Dec. 17, 1913

The President, Dr. C. P. Caldwell, in the Chair

SYMPOSIUM ON SURGICAL CONDITIONS OF THE KIDNEY

Pathology of Surgical Conditions

Dr. Henry Albert, Iowa City, Iowa: Accessory renal arteries occur in about 20 per cent. of the cases. Israel and Mayo have called attention to these accessory arteries in the production of hydronephrosis. It is easy to understand how, if the kidney is hypermovable, the ureter may frequently kink over such an accessory artery. Horseshoe kidney is also another anomaly. Such a condition may often interfere with the development of a pregnant uterus, and a pregnant uterus, by pressure on the ureters, may interfere with the flow of urine. Complete anuria is apparently not very common. It is also interesting to know how long a patient may live with a complete anuria. Morris reports cases in which one patient survived seventeen, and another twenty-three days.

Quite obviously, the most common route of infection is the hematogenous by means of the renal artery, the so-called descending infection. We also have infection by the renal vein, but we ordinarily think of ascending infection by way of the ureter. It seems probable that that mode of infection is rather rare. It is possible, however, in two ways—either from passing into the bladder by continuity of tissue along the mucosa, gradually extending up to the kidney, or by the bacteria going into the urine and passing up the lumen. Against such infection there are two obstacles: first, the more or less constant flushing out of the ureters by the downward flow of urine; second, bivalve action of the ureter wall by passing the urine through it. In case of obstruction we have the flushing effect gone, and bacteria once gaining entrance past the area of obstruction may gain access to the kidney, and likewise the bivalve action may be destroyed.

Quite recently Sampson, by injection methods, demonstrated a communication between the blood-vessels of the kidney and of the bladder by means of anastomosis occurring with the blood-vessels of the ureter. He likewise demonstrated a communication between the blood-vessels of the kidney and bladder by way of the blood-vessels of the uterus and ovaries. Serota was in favor of the lymphatic route and has found that the lymph-vessels were principally distributed to the lower pole and pelvis of the kidney. Kumita finds that the most important lymphatic communication between the ureter and kidney was by way of the lymph-vessels communicating with the ureter, going first of all to the capsule of the kidney, and then to the kidney substance. This no doubt explains the cases that have been reported of a cystitis and a perinephritis with multiple abscesses of the kidney without any involvement of the ureter. Frank has also demonstrated some lymphatic communications between the ascending colon and the kidney in rabbits, but I have not seen any confirmatory evidence of his work. It seems from the work of Stewart on the production of infection in cases of transplantation of the ureter into the intestines, in which there is very good opportunity for bacteria to pass upward, that the most important of the ascending groups of infection is by way of the lymph-vessels rather than by way of the ureter.

While tuberculosis of the kidney is always a secondary process, nevertheless, tuberculosis, as regards the urinary organs, is no doubt almost always a primary process in the kidney. The chronic localized or ulcerative form appears to be for a long time a unilateral process; but if it continues for a long time it becomes more and more marked and also involves the other kidney. There is some question as to the route by which the other kidney is most affected, whether by ascending infection or by way of the blood-vessels. It seems most likely that it is an ascending process; that is, tubercle bacilli in the bladder gaining access through the ureter and passing up, but it seems from studying many specimens that the other is the more common route.

The most interesting of all kidney tumors is hypernephroma. It is supposed to have its origin in the adrenal structure, and is, as a rule, quite well encapsulated from the kidney. There has been some discussion by Adami and Wilson as to the origin of these tumors, but I believe that the term "hypernephroma" should be applied to those tumors, however rare, which really have their origin from the adrenal gland structure.

Methods of Diagnosis in Surgical Conditions

Dr. Bransford Lewis, St. Louis: Many evidences, widely accepted as pointing to kidney disease, do not justly command such a position. Some have no relation to kidney disease, while others mislead as to which kidney is diseased and which is healthy. Nine-tenths of the instances of pain in the back come from muscular rheumatism or some such simple cause, without any involvement of the kidneys. Thus, this symptom, which is widely credited by the laity, is recognized as a fallacy in that light by the profession; but the profession in general is not so familiar with the oft-noted fact that pain arising in a diseased kidney may be transferred or reflected into the healthy one, affording material, but possibly very misleading, evidence in the case. This is a comparatively frequent source of error in renal surgical cases. In the necropsy room kidneys are found riddled and honeycombed with pockets and cavities containing stones, but with never a characteristic renal symptom in the record. On the other hand, I have seen numerous instances in which symptoms and signs were typical of renal or ureteral stone, and yet subsequent developments proved that no stone was present. The attack was due to uric acid crisis and renal irritation.

There is one condition of renal pathology in which symptoms seem to outweigh the signs in certain respects, namely, acute hematogenous infection, in which the affected kidney is so overwhelmed with the toxic effect that not only does it fail to give the alarm by pain, but also its functional activity may be suspended, and it fails to give material evidences in the urine, such as blood and pus. In such cases the symptoms are those of toxemia rather than of acute nephritis or pyelonephritis, as ordinarily understood. Yet even in these, as in cases of unilateral anuria from blocking of the ureter, the very absence of urine from that side, as determined by ureteral catheterization, is negative evidence of great value, and is to be learned by ureteral catheterization.

How are we to view and utilize the attendant symptomatology when present in studying renal cases? The many symptoms taken collectively should direct the physician's attention to the necessity of making a complete physical examination. The steps of a physical examination for disease of the upper urinary tract necessarily vary according to the circumstances of each case, but they should embrace measures and means that will furnish definite and accurate information regarding the physical condition and functional activity of the organs involved, together with those of the allied organs, the heart, liver and digestive apparatus.

Functional Tests and Their Importance in Renal Surgery

Dr. E. G. Mark, Kansas City, Mo.: Most of the various tests proposed for the purpose of determining the functional capacity of the kidney have fallen into a state of desuetude. Cryoscopy, while severely criticized by Israel, Robson and others, is still employed by many. It should not be advocated as being absolutely dependable, but it is of great value. One of the strongest arguments in its favor is its practicability as a routine measure. Instruments of the highest degree of perfection must be employed, as even under the best conditions the possibility of error is great. The phloridzin test has been proved by Caspar and Richter to be valuable, but, as in cryoscopy, it can in no way be considered dependable. The newest test, the phenolsulphonephthalein test, has had a surprisingly wide acceptance, and the findings of the different investigators have been remarkably constant. It is simple of performance and requires no particular refinement of technic. It is my belief that it is by far the most reliable and valuable of the so-called kidney function tests, and in my hands the findings have been most striking and dependable. I have by choice employed the intravenous method of injection, although I see no objection to the intramuscular technic. Microscopic amounts of blood in the urine may interfere with accurate readings. The advantages claimed for this test are: (1) complete elimination of the drug by the kidney; (2) early appearance of the drug in the urine following administration; (3) rapid excretion of the drug by the kidney, necessitating observation for only one or two hours; (4) brilliancy of the color which is imparted to the urine, and which is not readily influenced by the coloring matter of the urine itself; (5) the possibility with which this drug makes accurate quantitative examination possible; (6) simplicity of technic; (7) absolute non-toxicity of the drug; (8) non-irritating quality of the drug, and (9) absence of extra strain placed on the kidney during the test.

None of the tests are absolute or infallible, and repeated tests should be made. Further, let me urge the importance and common sense of thorough clinical observation, from all points of view, and the value and necessity of the older and generally accepted means of qualitative and quantitative urinalysis.

The Treatment of Surgical Diseases of the Kidney

Dr. L. W. Bremermann, Chicago: The treatment of these diseases resolves itself into three very important factors, namely, when not to operate, when to operate, and what definite method of operation to employ. To my way of thinking, when not to operate is of greater consequence than any of the other methods of treatment already mentioned. It depends entirely on the diagnosis and the extent of the pathologic process—also on whether the lesion is unilateral or bilateral; on whether there may be a congenital renal defect demonstrated as a single organ, a fused or horseshoe organ, etc., and on whether the renal lesion may be secondary to a lesion elsewhere in the body, producing such an amount of constitutional impairment that surgical treatment would be followed by disastrous consequences. With correct recognition of the scientific facts discovered by our method of diagnosis, we may find conditions which will not warrant hasty treatment of a surgical character, yet with the institution of medical, hygienic and dietary measures the lowered resistance of the patient may be so improved and the functional capacity of the kidneys may be restored to such an extent that surgical treatment may subsequently be carried out safely.

From the point of view of when not to operate, the surgeon must weigh carefully all of the facts at hand; whether the condition is unilateral or bilateral, the degree of mobility, the amount of danger of destruction of the organ and the character of the symptoms. In bilateral renal tuberculosis it is the opinion of some that an operative procedure should be performed on the organ which shows the greater amount of destruction, yet great judgment from large experience is necessary before one can decide absolutely whether nephrectomy or a nephrotomy should be done. I believe that the patient has a far better chance of recovery if a nephrectomy is done in this type of cases—followed by constitutional hygienic and dietary treatment, including the careful and scientific administration of vaccines and tuberculin. In cases of definite unilateral tuberculosis, in which a nephrectomy is indicated from the study of the patient, careful after-treatment, including tuberculin, is always indicated, and must be carefully attended to, as it is the consensus of opinion among urologists that renal tuberculosis is secondary to tuberculosis elsewhere in the body, although many times the primary focus cannot be located clinically.

When to operate depends entirely on exclusion and one arrives at a definite opinion only after all of the factors revolving around the question of when not to operate have been considered and cast aside. The operative technic depends on the judgment of the individual operator to a great degree. I believe that for our opinion regarding the proper surgical procedure we are dependent on the estimation of the renal functional capacity more than on any other feature.

The treatment subsequent to all surgery on the kidney is vastly important. In all cases of renal pathology accompanied with infection, in which the bladder may be involved secondarily, a careful study of the case will clearly show the nature of the infection. Autogenous vaccines may be prepared and administered, together with hygienic and dietary measures. Likewise, in renal tuberculosis with mixed infection the same mode of treatment should be carried out, accompanied, of course, as before said, by the use of tuberculin. Every phase of the cases under observation should be taken into consideration. All points should be considered from the patient's point of view, and with the idea of prognosis continually in the mind's eye, for the purpose of reaching favorable end-results. The surgery of the kidney and urogenital tract has advanced more in the last decade than any other branch of surgery, from the point of view of diagnosis and treatment, placing the work on a thoroughly scientific basis, so that the mortality has been markedly reduced. Every method and diagnostic aid must be employed, so that this mortality will be further decreased and more favorable results be obtained, particularly on account of the possibility of earlier diagnosis from an increased knowledge of genito-urinary surgery among general practitioners.

DISCUSSION

Dr. F. Kreissl: In the diagnosis of distentions of the renal pelvis, of hydronephrosis and pyelitis, with distention of the renal pelvis, I admit that the injection of collargol, followed by roentgenography, is a very efficient means of demonstrating the real condition present, but years ago I devised a simple means to arrive at the same diagnosis. If a ureteral catheter is introduced into a normal renal pelvis which is not distended, a few drops of urine are found coming out; but if the urine is found coming out as if through a catheter introduced into an overdistended bladder, the renal pelvis is distended. From the quantity collected in this way the exact size of the distended renal pelvis can be estimated.

I have noticed that whenever anything is said about the diagnosis of the function of the kidney, there is one point overlooked, namely, not to establish what the kidney will do ordinarily, but to establish what it will do when put under a special strain. It is important for us to know in what condition the other kidney is before we perform a surgical operation on the kidney. If we want to perform a nephrotomy it is important for us to know not only the condition of the kidney to be operated on, but also that of the other kidney. Why? The question might come up, Is the condition of the kidney to be operated on such that it is desirable to preserve it or that it becomes imperative to preserve it? I merely refer to those cases in which bilateral kidney disease exists. When it comes to nephrectomy, it is absolutely necessary for us to know what the kidney will do under ordinary circumstances, if functionally intact, and if it has enough latent or reserve force to take up the functions of both kidneys after the operation.

It is agreed by a large majority of men engaged in kidney surgery that cryoscopy, not alone, but in combination with experimental polyuria, is a reliable means of establishing a diagnosis. I have not done very much work with the phenolsulphonephthalein test, but from what I have seen and heard I believe that it ranks practically as high as the combination of cryoscopy and experimental polyuria.

Dr. William Fuller: I think that if early diagnosis of kidney and ureteral lesions is accomplished we shall change our surgery of the ureters and kidney, and that we shall see more of those cases which indicate a partial nephrectomy, for such lesions as tuberculosis of the kidney. I am sure that in some cases there are isolated foci of tuberculosis in the kidney, and that such patients will recover just as quickly with partial as with total nephrectomy. We do not think of removing the entire shaft of the bone for localized tuberculosis; neither should we think of removing a kidney for tuberculosis in one part of the organ. Early diagnosis is the thing in kidney surgery. If we can make it accurately, and early enough, we shall find an opportunity for partial nephrectomy.

AMERICAN ASSOCIATION FOR STUDY AND PREVENTION OF INFANT MORTALITY

Fourth Annual Meeting, held in Washington, D. C., Nov. 14-17, 1913

(Continued from page 66)

Heat and Infant Mortality

Dr. J. W. Schereschewsky, Washington, D. C.: The most significant phenomenon in connection with the mortality of infants is the great increase of their deaths in the summer months. This increase is most marked in countries where the winters are cold and the summers hot. It may be absent in lands where the summers are habitually cool or in the tropics where there are but slight variations in the mean temperature throughout the year. In countries with cold winters an increase in infant mortality is perceptible whenever the mean temperature rises above 20 C. (68 F.). The deaths of infants show a striking parallelism with the curve of maximum temperatures, being numerous when the daily maxima are high and diminishing where they are low. This parallelism is most strikingly manifest in the first part of the summer. This phenomenon, however, holds good only when we compare the total infant deaths with the temperatures. On the other hand, when the deaths from intestinal diseases alone are compared with the maximum temperature, the early summer heat brings no great increase in their number. The death-curve from these diseases lags behind the curve of maximum temperatures to rise with almost explosive violence later in the summer, reaching its apex in July or August, according to the locality, and slowly declining through September and October. From 80 to 90 per cent. of the infants dying from intestinal diseases are artificially fed.

The great summer mortality of infants can be explained by three hypotheses only. The infants are killed: (*a*) directly by the heat; (*b*) by the action of stale or dirty milk and the contained bacteria, or (*c*) by specific infections.

The action of heat as a direct cause in the death of infants has hitherto been greatly underestimated. The lethal action of heat is a function not so much of the maximum and mean temperatures of the external air as of the indoor temperatures. The action of dirty and stale milk in causing the death of infants, while undoubtedly a contributory factor, has been given an importance which has overshadowed other factors of equal or greater significance. There is evidence to show that a certain proportion of infant deaths is due to specific infections, in the dissemination of which, contact infection and flies doubtless play a part. As a result, future activities for the prevention of infant mortality must concentrate themselves to a greater extent on the question of housing, especially with respect to the factors of overcrowding, narrow streets and presence or absence of thorough ventilation. The general public should be educated as to the importance of these factors in causing infants' deaths, and especially as to measures which will prevent children from suffering from the heat. Breast-feeding must still be regarded as a most, if not the most, important factor in reducing infant mortality.

DISCUSSION

Dr. T. B. Cooley, Detroit: There is a very obvious relation between summer heat and infant mortality. A great portion of the increased mortality during the summer is due to the action of summer heat in lowering the power of resistance of the child to certain factors, such as overfeeding, ill-judged feeding and spoiled food. Then comes the lower resistance of the child to infection and to the poisonous food elements. The troubles are chiefly indirect. We do not yet understand just how that indirect effect is produced. We do know that a great part of that effect can be avoided by improving housing conditions.

It is a very striking fact that almost the only thing which has been done that has had the effect to lower summer mortality has been the improving of housing conditions rather than improvement in the milk conditions. Housing conditions, heat, moisture, etc., inside of the house, and summer hygiene, aside from the question of feeding, must be attacked first. I think that a great deal of harm has been done by overemphasis on bad feeding. A large number of the general practitioners still believe that summer diarrhea is due to bad milk. So long as the profession continues to attribute summer diarrhea to that cause, not enough attention will be paid to the other causes of high summer mortality of infants.

Dr. I. A. Abt, Chicago: Several years ago I presented a paper on this subject at a meeting of the Section on Diseases of Children of the American Medical Association, which met in Los Angeles, and a great many doctors wondered what I was talking about. Those from New Mexico and Arizona and Southern California said that they had no such experience; they had no summer mortality. So there must be something besides the heat. There must be such an element as humidity that is not thoroughly understood. I think that some of these conditions are due to the debility caused by the heat. Every one is prostrated and not able to do his best, and that is true throughout the temperate zone. I presume that the baby feels it, especially if he is living in an insanitary home, or has been treated badly all winter. Babies bear extremes of temperature badly. Nobody has studied the effect that cold would produce. I do not believe that a baby would be able to stand excessive cold any more than excessive heat. Every one knows that arctic explorers are rendered feeble, and many die on account of the effects of long-continued cold, and those who travel in the tropics tell us that the debility is very great. Dr. Epstein has had a large number of deaths in his infant asylum. It seems to me that we make little progress when we tell people that dirty milk is bad and clean milk is good. Then without good and sufficient reasons are we willing to say it is not the milk at all? I think the best and the purest milk is none too good for the babies. I am in favor of pure certified milk.

Dr. Herman Schwarz, New York: We want not only good milk, but we want everything else that is good. Dr. Cooley certainly means that we should have pure milk, and I agree with him that pure milk is not the only thing. We need proper housing and adequate ventilation. In certain towns where the wind was in a certain direction, summer mortality was not known. As long as our houses are built as they are, block on block, we shall have summer infant mortality. We have not had enough cases yet to talk about. If there is a high temperature in the beginning of the summer, say in June, it will be found that infant mortality will be greater in July and August than it would be if June were not so hot. Those children have something in the beginning that reduces their vitality, and later on they cannot resist the heat and they die under even less heat as a result of the continued tax.

Dr. W. C. Woodward, Washington, D. C.: It is late in the day to begin to discuss the relation of milk to infant mortality. The data pertaining to that subject are too numerous and too definite to permit of two opinions to any one who is familiar with the subject. This does not mean that there may not be other causes that contribute to infant mortality. It does not mean that housing is not one of these contributing causes. I should like to offer to any member of the association who is interested in statistical study a statement published in the annual report of the health department of the District of Columbia, showing the number of deaths of children for the period from 1882 to 1902, by days, during the first five days of life. You will find in the same table for the same dates a statement of the dry-bulb thermometer, a statement of the wet-bulb thermometer, and the wind at 8 a. m. and 8 p. m.

Dr. F. W. Pinneo, Newark, N. J.: When we started a rather extensive infant-consultation service in Newark, many of the infants that came to us the first summer had diarrhea and continued to have it in spite of what we gave them. The next summer very few came with diarrhea, and during the past two summers we hardly ever had a case of diarrhea. I believe that the diarrhea at first was due to the fact that the babies had been fed improperly and with poor judgment. The main thing is to feed the infant correctly from birth.

We have emphasized in our work that at the first approach of warm weather the feeding must be cut down.

Infant Mortality in the Light of Eugenic Ideals.

Dr. H. E. Jordan, Charlottesville, Va.: In organic development both heredity and environment are absolutely essential; moreover, the action of the one complements that of the other. If the environment is baneful or deficient in any one of many possible ways, one expression of the effect will be in increasing infant mortality. Similarly, if the inheritance be of low quality or defective the prevalence of infant mortality will be extended. About 10 per cent. of our population is estimated to be defective and so a racial menace. If we succeed in raising all infants, obviously some unfit stock will be raised to reproduce its defective type, thus working injury to the race. Theoretically, a certain small amount of differential infant mortality must obviously be a good thing. But even if morally and socially allowable—which it is not—no discriminating procedure would be practical, for it is impossible by present means to distinguish absolutely and certainly in early infancy between the potentially fit and strong and the grossly unfit and weak. We cannot lower our ideal. The same serious effort must be made to rear all infants. But at the same time we must recognize the fact that some unfit stock, reproducing in geometric ratio, is thus saved to reproduce its defective type and to contaminate the race. This simply means that our efforts for infant conservation must be extended to embrace an interest also in potential parents and to seek means to prevent reproduction on the part of those seriously deficient racially. Our efforts may defeat our aims unless the mass of the babies we save are racially of sound stock.

Dr. Henry Schwarz, St. Louis: Taking care of the health of prospective mothers and preparing them physically and mentally for their task of nursing and raising their offspring is the first and the most important step in the conservation of infant life. At present only a small percentage of expectant mothers receive proper attention during gestation, and every year thousands of mothers and babies die or are permanently injured, whose lives and whose health could have been preserved by reasonable prenatal care. Factors at work to bring about a betterment of conditions includes improvements in obstetric teaching; establishment and extension of obstetric dispensaries, and attempts to impart much-needed information to expectant mothers through the missionary educational work of prenatal nurses, and through the publications of the United States Children's Bureau.

2. **Thyroid-Tissue Tumors of Ovary.**—In certain ovarian tumors, as for instance those cited by Outerbridge, there occur areas of tissue which cannot be distinguished histologically from that of the thyroid. Between tumors which show a complex teratomatous structure, containing among numerous other elements a small amount of thyroid tissue, and those composed solely of this, there is no sharp dividing line. All these tumors are of similar genesis; they are teratomas, with varying degrees of suppression of the ectodermic and mesodermic elements. The large majority of these tumors are clinically benign; the few which are malignant show, in most instances, areas of unmistakable irregularity in their cellular structure, or give other histologic evidence of having assumed a destructive type of growth. The thyroid tissue in the ovary is of no functional significance, at least in the vast majority of cases, and these growths give rise to no symptoms other than those which would be produced by any type of ovarian tumor of equal size. The term "teratoma thyroidiale ovarii" is suggested as the most satisfactory designation for those tumors in which the thyroid tissue forms the dominant feature. Almost fifty recorded cases are analyzed.

3. **Sarcomatous Change in Uterine Fibromyomas.**—In a study of 250 cases of uterine and cervical fibromyomas Geist found that twelve showed sarcomatous changes of various types. In most instances (9 cases) the myomas were multiple with a solitary focus of sarcomatous change. In but one instance were there multiple sarcomatous areas. Microscopically the sarcomas presented either pure spindle-cell type (5 cases), pure round-cell (1 case), or a mixture of both (6 cases). The latter type contained varying numbers of giant cells. In two of his twelve cases sarcomas were found in fibromyomas, where he could trace the progressive stages of the transition from normal muscle into sarcoma. The narrow muscle cells with their slender nuclei become larger, broader and more rounded, the nuclei also become larger, the chromatin gradually increasing in amount. In some cells the chromatin is irregularly arranged in small masses, in others it is more uniformly distributed in one large rounded or elongated mass occupying almost the entire cell. Occasional mitotic figures are seen in the transitional areas, the number of which gradually increases until in the midst of the sarcoma tissue one can often find two or three figures in each field. In the transitional zones the cells keep within the bounds of the normal fascicular arrangement and direction of the muscle bundles. In these two cases Geist was able to trace the transition from the myomatous tissue of the fibromyoma into sarcoma, and he says there can be no doubt raised as to the origin of the sarcoma from the muscle cells of a fibromyoma.

13. Abstracted in The Journal, May 21, p. 1737.

14. **Tumors of Carotid Body.**—The authors review sixty cases of tumors of the carotid body recorded in the literature,

including their case. In the 60 cases, 4 have been found at autopsy. Two were examined post mortem, although the existence of a tumor had been known when death occurred from other cause. The remaining 54 cases have come to operation. In 4 the tumor was laid bare, only to find such extensive involvement that nothing could be done. All three carotids were ligated in 32 cases, the external only in 7 cases. In 15 cases the tumor was dissected away from the common or internal carotids after ligation of the external. In 8 cases recurrence took place, in 6 of these after the tumor had been dissected away from the blood-vessels, in 2 cases after complete removal of all the carotids. In 1 patient examined after death there were metastases in the liver. Of the 54 patients operated on, 42 have recovered and 12 died. But to these 12 deaths must be added 4 from recurrence and 6 other speedy deaths in prospect from recurrences known to exist when the case was reported, or 22 deaths in 54 cases. In 1 other case the patient probably died as a result of the tumor.

The causes of death have been: In 4 cases, pneumonia, in all of which the pneumogastric was divided or resected at the operation; in 3 cases, hemorrhage; in 2 cases, cerebral anemia; in 1 case, acute edema of the lungs; not stated, in 1 case; in 1 case, septicemia; in 1 case, infection and hemorrhage. In addition to this mortality, however, other accidents have arisen in the patients who survived. In 4 cases, the patients have had hemiplegia with aphasia. In 4 the voice has been affected, and there has been more or less dysphagia. In one there has been such tracheal irritation as to produce a constant cough. In 5 the tongue has deviated to one side. In 4 there has been an altered pupil, in 1 conjunctival injection. In 4 cases the face has been party paralyzed.

26. **Cardioneurosis.**—Generally speaking, Abrahams says, cardioneurosis planted on an organic lesion is fairly amenable to treatment. The organic trouble gives one an excuse for putting the patient to bed, and rest in bed is an essential part of the treatment of neurosis. Disturbance minus a lesion is also a reason for sending the patient to bed, but the patient will argue against it and his opinion, in the long run, prevails. Some things, at least, are within our power to recommend: early to bed; avoidance of excitement; abstinence from coffee, tea and tobacco; scrupulous regard for overfeeding and sluggish action of the bowels. Cardiac stimulants such as digitalis, strophantus and the members of the coffee family are harmful, unless, of course, the disturbance is a natural expression of a heart lesion; if so, that would be a matter of diagnosis. Sedatives are more useful and the best to Abrahams' knowledge is ammonium bromid in doses of 15 grains three times a day, or one dose at bedtime. Massage and hydrotherapy are useful; the Nauheim bath, both the real as well as the homemade one, is useless. Diuretin in 5-grain dosage three times a day is valuable in cases in which the neurosis is associated with arteriosclerosis. With causes so varied, with manifestations so complex, Abrahams concludes that each case of cardioneurosis shall be considered an entity and be studied in its kaleidoscopic patterns.

27. **Hypothyrosis and Urinary Tract.**—In four cases of hypothyrosis with urinary symptoms, that Stern examined cystoscopically, anatomic alterations of apparent hypothyrogenous origin could be demonstrated. That the alterations in the bladder or urethra were entirely dependent on the hypothyroid state was evidenced by their decline and increase corresponding to the fall and rise of the other hypothyroid phenomena on the exhibition or withdrawal of thyroid preparations. That the urinary symptoms were caused by the hypothyroid modification of the local structures became manifest by their disappearance when the local process abated, and their reappearance on the recurrence of the mucosa infiltration. The mucous membrane was edematous and swollen. Stern suggests that in cases of frequent or painful micturition a general hypothyrotic state with manifestations in the lower urinary tract must be thought of, and that a cystoscopic examination of the latter be made. Further, that, possibly frequent or painful micturition may be an early, and as such for a time the only subjective phenomenon of import in hypothyrosis, and that a cystoscopic examination be undertaken. Finally he points out that enuresis in children as well as in adults may be due to a hypothyrotic or kindred origin, that the cures of such cases after the administration of thyroid substance, as reported by French and other physicians, may be due to the disappearance of myxedematous swellings from the lower urinary tract, and that in instances of persistent bedwetting a cystoscopic investigation be insisted on.

28. **Early Symptom of Pernicious Anemia.**—Periodical soreness of the tongue, gums and palate, Stern believes, is without question the most reliable of the inaugural symptoms of pernicious anemia. For some time this symptom has been known to occur in the course of the affection, at a stage when its clinical and hematologic picture is fully developed. Stern has observed this symptom in the initial stages of two cases of genuine pernicious anemia, one of which has since terminated lethally, and in another apparent case of the affection which is still under observation in which, however, the blood-picture is not absolutely characteristic.

34. **Ophthalmo-Tuberculin Reaction.**—Gutman favors the ophthalmo-tuberculin reaction. He says that the test is absolutely without danger, safe, very reliable and serves the purpose as well if not better than the Pirquet. He does not know of a single case in which the test has proven dangerous. He cautions, however, that the test should never be applied to an eye unless nothing wrong is found about it. If one eye is in good condition while the other one is not, the test may be applied to the good one.

36. **Diagnostic Sign for Lesions at Pylorus.**—A small, circumscribed spot of "wincing" tenderness, Skillern says, is a common sign in gastric ulcer. With the patient reclining and the stomach empty, mark on the skin the site of the "wincing" tenderness. Now inflate the stomach with air. The pylorus shifts, carrying the spot of "wincing" tenderness with it. The lesion, then, must be in the pylorus and not elsewhere. This lesion is probably an ulcer of the pylorus. If the spot of tenderness does not move, the pylorus is either not involved or, if involved, is firmly anchored by adhesions, and these adhesions are due more often to infection of the biliary tract than to pyloric ulcer.

47. **Implantation of Joints.**—Implantation of joints in Eloesser's opinion is a feasible and useful procedure. Much of the implanted bone becomes necrotic; it is not shed, however, but amalgamates, and is absorbed and replaced by living bone. A small part of the implanted bone remains alive, viz: the superficial inner and outer layers. Much of the implanted periosteum and endosteum remains alive, and is probably the source of the new bone. A subsequent arthritis deformans does ont seem to develop in the new joints. The fresh cadavers of patients who have died suddenly of a noninfectious disease should be used. Absence of infectiousness should be assured by bacteriologic and serologic tests. Eloesser cites two cases.

66 *Mechanism of Action of Hexamethylenamin. P. J. Hanzlik, Cleveland.

66. **Hexamethylenamin.**—Following the administration of hexamethylenamin, Hanzlik found that the substance itself can be detected in all of the body fluids. Free formaldehyd does not appear in any of the body fluids which are neutral or truly alkaline. This includes blood, cerebrospinal, pleural, pericardial and synovial fluids, aqueous and vitreous humors, saliva, bile and some urines. Urines which are truly acid and contain hexamethylenamin practically always contain formaldehyd. Urine is the only body fluid, except gastric juice, which exhibits true acidity, hence it is here only that liberation of formaldehyd from hexamethylenamin can take place. The same general law applies to pathologic fluids. From the correlation of chemical experiments with bacteriologic and clinical data, Hanzlik states that hexamethylenamin acts as an antiseptic only in proportion as it liberates formaldehyd, and that this liberation can only occur when the reaction is truly acid.

Free formaldehyd is an efficient bactericide in comparatively high dilutions. Such an efficient concentration can be attained in normally acid urine. It is only in vesico-urinary conditions where one can expect any beneficial therapeutic action after the administration of hexamethylenamin, because urine is the only body fluid whose reaction may be altered, if necessary, to such an extent that liberation of formaldehyd with other body fluids in as much as their neutrality or a slight tendency to alkalinity is rigidly maintained. No beneficial therapeutic responses therefore are to be expected in meningeal infections; infections of the cerebrospinal fluid or about the spinal cord, bile or biliary passages; or of the infections of the ear, eye, synovial, pericardial or pleural fluids. On account of the rapid absorption of hexamethylenamin and of the usual alkalinity of the bowel contents, no bactericidal action can be expected in the intestinal canal.

It was also shown in Hanzlik's experiments that the administration of monosodium phosphate (NaH_2PO_4) does not alter the reaction of the fluid from the intestines, and that the hexamethylenamin present under such conditions passes through the bowel unchanged. However, the administration of the monosodium phosphate increased the true acidity of the urine and the concentration of formaldehyd in such a urine containing hexamethylenamin is markedly increased. Therefore in the urine an opportunity presents itself to increase the efficiency of hexamethylenamin therapy. This can be accomplished by the administration of the monosodium phosphate until the urine when tested with the phloroglucin reagent gives a reaction for formaldehyd.

This test indicates quite closely the turning point in the reaction of urine. That is, at approximately the point of neutrality or beginning alkalinity it will no longer give a positive formaldehyd test with a hexamethylenamin urine, but as soon as such a urine begins to be truly acid, it gives a positive test for formaldehyd. A urine which has been previously alkaline, that is, possessing a hydrogen ion concentration of 7.2, can be rendered acid, that is, increased to a hydrogen concentration of 4.85 within approximately five hours after the administration of 13 grams (200 grains) of the phosphate. If the occurrence of diarrhea is objectionable, the dosage of the phosphate may be reduced. On the other hand, the administration of alkalies, such as sodium bicarbonate ($NaHCO_3$) or potassium citrate, entirely prevents the benefits of hexamethylenamin; and it is, therefore, irrational to prescribe them together.

82. **Specific Paratuberculous Enteritis of Cattle.**—The paratuberculosis enteritis found in America, Meyer says, is identical with the disease of European countries. By intravenous inoculations with material from the mesenteric lymph-nodes the disease has been reproduced in young calves (30, 92 and 96 days of age). The incubation time was from four to eight months. One animal died from the disease twelve months after the infection. Feeding experiments were not successful. The natural infection probably takes place in the early days of life by contact with infected mothers or surroundings. The possibility of an infection in certain pastures, where *B. paratuberculosis* leads a saprophytic life, Meyer believes, cannot be denied, and is probably of importance for the infection of adults. *B. paratuberculosis* can be cultivated on solid and liquid culture media containing glycerin extracts of acid-fast bacilli, particularly tubercle bacilli or *B. phlei.* Six strains have so far been isolated. The growth is slow and only possible at body temperature. A culture medium consisting of equal parts of tuberculin and bouillon, with a 2 per cent. agar and 1 per cent. serum, is the best for primary isolations. Meyer maintains that the use of antiformin should be limited to contaminated material. The bacterioscopic examination of feces and rectal scrapings is only of diagnostic value in about 40 per cent. of the cases in the advanced stages of the disease. Avian tuberculin is an unreliable reagent for paratuberculosis. "Paratuberculin" and perhaps some of the serum tests may prove in the future to be more reliable. *B. paratuberculosis* is, in certain respects, related to different representatives of the acid-fast group of bacteria.

83. **Relation of Hodgkin's Disease.**—It is held by Oliver that Hodgkin's disease must be classed with the lymphosarcomas and endotheliomas of the lymph-nodes as a neoplastic process. The following facts compel this conclusion: (a) the similarity, and in cases identity, of the histologic process; (b) the early and constant development of malignancy (invasion of capsule and veins); (c) the ultimate formation of true metastases, partly at least by the blood-stream. The endotheliomas of the lymph-nodes are of relative frequent occurrence and are classed by Oliver as endothelioma medullare, endothelioma scirrhosum and endothelioma cylindricum (Winigradow), or better by the classification of Ewing as diffuse, alveolar and perivascular.

84. **Primary Hodgkin's Disease of Spleen.**—In Wade's case there was at no time any enlargement of the superficial lymph-nodes, nor was there evidence of any lymphatic hyperplasia within the mediastinum or abdominal cavity. The disease was of long standing in the spleen as was evidenced by the gross and histopathologic appearance. Therefore, Wade believes, it should be considered one of primary Hodgkin's disease of the spleen, a condition quite unique, but one, he says, that occurs more frequently than has been held. Some of the reported cases of primary splenic sarcoma may easily have been unrecognized Hodgkin's disease.

85. **Diet Studies in Transplantable Tumors.**—It has long been a popular belief that the character of the diet of a group or race of people bears an important relationship to the incidence of malignant growths. The experiments reported by Van Alstyne and Beebe may be divided into two classes: 1. Those experiments in which one group of animals was kept on a special diet for from three weeks to two months before being planted with the tumor. A group of thirty-four white rats of uniform age and weight was divided, without exercising special selection, into two groups of seventeen rats each. One group was placed immediately on the special non-carbohydrate diet which consisted of casein and lard. The second group was continued on the ordinary laboratory diet, consisting of bread. This feeding was continued for a period of six weeks, at which time the animals were all planted from the same seed.

In this experiment the tumor was a Buffalo sarcoma. A large mass of the tumor was removed, finely pulverized and suspended in salt solution. Of the emulsion thus prepared each rat received one cubic centimeter by subcutaneous injection. The animals of both sets were in good physical condition at the time of planting the tumor. I. Non-carbohydrate diet: 17 rats planted: 7 takes: 4 retrogressed; 2 killed by the tumor; 1 died from unknown causes. II. Experiments in which the special feeding of the animals was begun on the same day that they were planted. In this group there was a total of 27 rats, divided into two lots, 13 being placed on the regular diet and 14 on the non-carbohydrate diet. The same diet was used as in the previous experiment, and the animals were fed for six weeks before being planted. The methods of planting these rats was the same as that followed in experiment I, a freshly removed tumor serving as the seed for all of the animals: 14 rats planted: 1 take: 1 rat took the tumor, which grew to large size and killed the animal. Regular diet: 13 rats planted: 7 takes: 3 died from unknown causes; 4 killed by the tumor. The results in this experiment are so striking that the authors claim one can scarcely avoid the conclusion that the preparation of one group of animals by feeding on a non-carbohydrate diet has enabled the animals to resist the tumor.

86. **Studies in Anaphylaxis.**—The conclusion drawn by Weil in a previous paper is verified, namely, that the mode of sensitization determines certain important factors in active anaphylaxis. Guinea-pigs sensitized by the injection of fractional amounts of alien serum present a prolonged incubation period, require a relatively small dose of antigen to produce death and contain in their serum relatively few specific antibodies. On the contrary, guinea-pigs sensitized by repeated large injections of alien serum present an abbreviated incubation period require a much larger dose of antigen to produce death, and have many more antibodies in their serum. To these data is added the fact that after active sensitization by fractional amounts of alien serum, the minimal desensitizing dose is relatively very small. After sensitization by repeated doses, the minimal desensitizing dose is many times as large as in the previous case, and may even very largely exceed the minimal lethal dose there determined. After the passive sensitization of guinea-pigs by small and by large amounts of immune rabbit serum, respectively, it is found that the minimal desensitizing doses are small and large respectively. Hence the deduction is drawn that in active anaphylaxis also the amount of the minimal desensitizing dose is determined by the relative number of specific antibodies possessed by the animals. Repeated desensitizing injections ("doses subintrantes") are subject to the same conditions as control the effectiveness of the single dose. Moreover, it is shown that recovery from severe anaphylactic symptoms, or from the administration of a dose fatal for control animals, does not necessarily avert a fatal result on the administration of a larger dose on the succeeding day.

Cases are cited to show that human beings are sensitized, in the same way as are guinea-pigs, by the repeated injection of large amounts of therapeutic serum, given intraspinally, and may be killed by a subsequent injection. The desensitization of these individuals offers a complex problem, which is discussed in detail. Protection against the toxic effects of primary injections presents a problem of the same character, but probably much less difficult of solution.

88. **Disease Importance of Pulmonary Anthracosis.**—Summarizing the various points indicating the disease importance of anthracosis which Haythorn has gathered from histologic evidence, he draws the following conclusions: Moderate anthracosis in an otherwise normal lung is not in itself detrimental to health. In tuberculosis and granulomatous conditions in which the reactions are chiefly centered in focal lesions of the tissues, the anthracotic condition is either entirely passive or is active in assisting healing, in that it is an additional stimulus to fibrosis and encapsulation and in that it aids in the localization of the process through the obliteration of the lymph spaces. In acute inflammatory conditions in which the lymphatics are important for proper

resolution, anthracosis becomes seriously detrimental, because of the obliteration of these spaces.

105. **Treatment of Ventral Hernia.**—The details of Haynes' inversion method are as follows: Dissect the skin from the sac and the skin and fat from the fascia for a distance of from one to two inches beyond the margin of the hernial orifice. Whether the skin shall be entirely removed from the sac depends on whether the sac is to be inverted entire or not. The preceeding case is the only one in which it was necessary, or seemed necessary, to accomplish the technic without opening the sac. In all the other cases the sac was opened to deal with some attending complication. In these instances more or less skin was removed by the usual eliptical incisions with the redundant portions of the sac itself. After the complications have been dealt with and the sac (peritoneum and thin fascia) has been sutured with No. 2 plain gut, doubled, the inversion of the hernia and coaptation of the margin is carried out. For this purpose two rows of sutures of heavy kangaroo tendon are necessary. Both rows are placed mattress-wise with deep and wide bites in the external fascia, the two rows "break joints" with each other. Retention sutures of either bronze wire, silk-worm or chromic gut are used to take the strain off the mattress sutures. The wire is preferred in the larger hernia and the gut may be used in the smaller ones. These sutures are placed in the figure-of-eight manner and brought out through the skin at a distance of from two to four inches from the skin incision where they are tied firmly over the rolls of gauze or a large rubber tubing (quill suture). A drain of rubber tissues should be inserted before the skin is closed with silk-worm or plain gut.

106. **Ovarian Disease and Production of Sterility.**—Forty-five cases have been collected by Kosmak from various operators as regards the relief of sterility and also on the effect of the removal of one ovary on the sex of the child. There were seven cases of extra-uterine pregnancy in the series in which the ovary was removed in connection with the ruptured tube, otherwise the ordinary cystic degeneration served as the reason for the oophorectomy except in a few instances where salpingo-oophorectomy with adhesion was given as the cause. In nine cases a uterine suspensory operation was done and likewise an appendectomy. In twenty cases children were born previous to the removal of the ovary. As regards the sex of children born subsequently, the sex changed in four cases and remained unchanged in seven where children of one sex had been born previously. In three cases with more than two previous children of different sexes, the sex after oophorectomy followed the preponderating sex previously. In one case in which 5 female children had been born there were 2 males and 1 female in the succeeding births, and in another in which 4 females were born a male subsequently resulted.

An attempt to relate the sex to the removal of one or the other ovary was therefore unsuccessful, as in the series of 45 cases there were 16 male and 13 female infants following the removal of the right ovary, and 16 male and 15 female infants following the removal of the left ovary—a fairly equal division of the sexes.

In the 19 cases of the series in which pregnancy had not preceded the operation, the oophorectomy was done in 3 women while still single and in 7 in a year or less after marriage. In the remainder the operation was done in from four to ten years after marriage. In 3 cases pregnancy took place in less than a year, in 10 cases in less than two years and in 3 cases between five and six years, although several abortions occurred in one of the latter series. As regards the sex of these children, in cases in which the left ovary was removed there were 8 males and 9 females subsequently born, and in those instances in which the right ovary was removed there were 5 males and 8 females.

Kosmak emphasizes that the question of sterility in an otherwise healthy woman must depend on an aggregation of factors rather than on a single lesion and that in every instance the entire pelvic contents must be subjected to careful study. In a certain proportion of cases, however, the removal of an ovary which is diseased undoubtedly contributes to increased function in the other, as evidenced by an improvement in the menstrual conditions and the greater possibility of subsequent pregnancies. It would appear as if the question of sex was not dependent on the side from which the individual ovum is derived and that whether the left or right ovary is removed the proportion of sexes in subsequent children is about equal.

123. **Acromial Breathing in Tuberculous.**—In looking over the histories of 52 cases, consisting of 28 in the first stage, 14 in the second and 10 in the third, Magida found acromial breathing present in all the first stage cases, in 8 of the second and 2 of the third. It would seem that it is a valuable method in first stage cases, and since that stage is the most important from a diagnostic point of view, and as the method is so easily acquired, the author believes it should be universally employed. It should also help toward ascertaining the advanced stages of tuberculosis, as the further advanced a case is the less probability there is of getting evidence from auscultation of the acromion process.

This method was first described by Robert Abrahams, who observed that in apical tuberculosis auscultation at the acromion process increases and amplifies all the auscultatory signs which are ordinarily obtained over the apices. The hard rubber bell is placed over the acromion process of the scapula, where it joins the acromion end of the clavicle. In thin people this anatomic part is not well covered with muscle and it is sometimes hard to place the bell of the stethoscope in such a manner as to exclude all external sounds. This, however, is overcome by pinching the skin up so that the bone fills the bell of the stethoscope; the surrounding folds of the skin act as a barrier to foreign sounds. Joint creakings which are sometimes heard are easy to distinguish from râles. The value of this method is best appreciated if the apices are examined first, the acromion later, and then the difference in the sounds compared.

125. **Bronchopneumonia in Children.**—Goltman outlines his course as follows: Support the patient's strength with nourishing liquid diet and let the temperature and pulse be guides as to whether stimulants should be used. The ice pack will reduce a temperature in quick time. When mucous rattling is heard, when the respirations are increased and dyspnea and cyanosis are present, aim at one thing—keep the respiratory center alive. Plunging the child into a warm bath and then wrapping it up in a cold sheet, pouring hot and cold water alternately from a height on the patient's chest will cause the child to cough and expel the mucus. Goltman has found that these measures are followed by good results.

131. **Inguinal Adenitis.**—To say that all cases of inguinal adenitis should be treated by incision and drainage, or that all cases should be treated by complete enucleation, Newell states, would be incorrect. Each case must be treated according to the condition found, to-wit: a simple, single bubo should be incised, curetted or wiped out; with the application of iodin or carbolic acid and gauze packing. Large masses of glands that belong to the superficial group, that are more or less circumscribed, that contain pus, but are not completely broken down, come out readily and easily in one ball-like mass when enucleated. And in Newell's opinion, this is the treatment of election in such conditions. If the deep glands are involved they should be removed cautiously along with the superficial one. The wound is closed and drainage is supplied at the lower angle. Large masses of glands with peri-adenitis and edema of subjacent parts, especially if they contain multiple abscesses, do better with free incision, curettage, partial enucleation and drainage. Tight bandaging, aspiration and the local application of heat, etc., have their place in the early treatment (abortive).

1. **Spontaneous Hemorrhage Sign of Disease.**—Bleeding from the nose is such a common event says Murray that even a sharp attack of epistaxis does not give rise to alarm unless it be unduly prolonged. In some persons it is readily started by a very slight injury and in others it occurs from time to time without any apparent reason, and careful examination may reveal no nasal disease to account for it. When epistaxis occurs with fever it may be an early symptom of enteric fever, especially if it is associated with frontal headache. The occurrence of epistaxis in granular kidney and arteriosclerosis is well known. A sudden attack of epistaxis occurring in a man who has passed middle age may be the first indication that he is suffering from granular kidney. This symptom naturally leads one to examine the urine, take the blood-pressure and make an ophthalmoscopic examination. Hemoptysis is by far commonest in pulmonary tuberculosis; it may be the earliest symptom to attract attention. Any hemorrhage from the lungs would naturally lead Murray to suspect pulmonary tuberculosis and take every pains to ascertain if it is present. An aneurysm or new growth in the lung or a pulmonary infarction may all cause a spitting of blood. Bronchial hemorrhage may be brisk and yet never recur. Hemorrhage from the gums may sometimes be mistaken for hemoptysis.

When blood is passed with the urine it may come from any part of the urinary tract, from the kidney down to the urethra. When blood comes from the kidney it is uniformly distributed through the urine. If small in amount it may make the urine "smoky," and there may be the "beef-tea" deposit; if abundant it may impart a bright red color to the urine. Blood which comes from the bladder or prostate appears chiefly at the end of micturition, as may be demonstrated by getting the patient to micturate into three different glasses in succession. Hematuria may occur in tuberculosis of the kidney and in the early stages of a new growth of the kidney, and may be produced also by the presence of a renal calculus. It may occur also in acute Bright's disease and in chronic granular kidney; in the former case the cause is generally obvious. A profuse attack of hematuria should always lead to a careful examination of the urine, the blood-pressure and the heart, to ascertain whether there is any evidence of a chronic granular kidney. In essential renal hematuria recurring attacks of hematuria take place, though it is rarely fatal. In cases in which an operation has been performed, the kidney has been found to be quite healthy, and in some the attacks have ceased after a simple nephrotomy.

In some cases presenting similar clinical features the hemorrhage has proved to be due to an angioma of a renal papilla, but these, Murray says, are not cases of "essential renal hematuria" and require a nephrectomy to remove the source of the hemorrhage. There is, however, another variety of attacks, of hematuria in which a single attack, or two or three attacks of hematuria occur close together, without subsequent recurrence. These may be termed examples of a good deal of anxiety at the time, as the loss of blood may be considerable. The absence of subsequent recurrences during a long period of years of good health shows clearly that in these cases there is no structural change in the kidney. Gastro-intestinal hemorrhages are in some cases very difficult to explain. Apart from bleeding due to actual ulceration, there is the hematemesis, which occurs in the early stages of splenic anemia or from the rupture of an esophageal varix in cases of alcoholic cirrhosis of the liver.

Secondary anemia and prolonged ill-health arise in some cases from small repeated hemorrhages, of almost daily occurrence, from hemorrhoids; the hemorrhage has been neglected by the patient and allowed to go on unchecked for years before medical advice is sought. In these cases the hemorrhage is not of importance as an indication of disease nor on account of the amount lost on any single occasion. It is the repeated small losses which impose so great a strain on the blood-forming organs that a profound secondary anemia results.

2. **Carcinoma of Uterus Cervix.**—The rules which Wilson has adopted for his guidance in these cases are as follows: (1) The iliac glands are not removed if, after the abdomen has been opened, they are not found to be enlarged, and the parametrium is clinically healthy. (2) If the patient's general condition is good and the parametrium is clinically infected, whether the iliac glands are enlarged or not, the larger operation is performed. (3) If a large mass of iliac glands is found, the operation is not proceeded with. By this time infection has spread far up the ovarian lymphatics to the lumbar glands, and no operation will cure the patient of her disease. Wilson emphasizes that something can be done, in an advanced case of the fungating type of growth where a large mass fills the vagina, and the patient is suffering from pain, a profuse, purulent vaginal discharge, and hemorrhage.

Of the various methods of treatment employed, Wilson believes none are better than a thorough use of the cautery, and the removal of all the exuberant portions of the growth by this means. The diathermic cautery is the best instrument to employ in Wilson's opinion, as the extent of its action is much more under the control of the surgeon than is the case with the actual cautery. The necrosis also, which the former instrument produces, is much less likely to be followed by an intense inflammatory reaction at the periphery of the growth, or by bursts of secondary hemorrhage later as the sloughs separate. Ligature of arteries is also useful in those cases in which hemorrhage and discharge are the prominent feature if the abdomen has been opened for the exploration of a growth which subsequently proves to be inoperable, it is quite a simple matter to ligature both main internal iliac arteries and one or both groups of ovarian vessels. This will cause a marked improvement in the symptoms for a time, but the results are not sufficiently permanent to justify a laparotomy for this procedure alone.

30 Three Cases of Glanders. H. M. M. Woodward and K. B. Clarke.

25. **Cancer of Prostate.**—Freyer is of the opinion that a prostate attacked by malignant disease previous to its undergoing adenomatous enlargement is rarely, if ever, capable of enucleation suprapubically by his method of dealing with hypertrophy of the prostate, or of being effectually removed by any other method, for the simple fact that by the time the symptoms declare themselves the disease has already passed through the capsule of the gland and invaded the adjacent structures. When, however, cancer supervenes on, or is due to degeneracy in, a previously enlarged adenomatous prostate, as very frequently happens, and the patient comes under observation while the prostate is still movable and the adjacent structures uninvolved—that is to say, while the malignant disease is still confined within the capsule of the gland—the prostate can, and should be, enucleated, Freyer's experience of operation under such conditions being most favorable. It is sometimes impossible to give a definite diagnosis of malignancy in such cases before the removal of the prostate, though the presence of hard nodules in the gland, combined with the rapid progress of the symptoms, will arouse strong suspicions which, Freyer says, should be communicated to the patient's relatives before operation is undertaken.

28. **Inoculation with Streptococcus Viridans.**—Small blocks from the right and left ventricles and auricles from nineteen hearts of rabbits in whom inoculation with the endocarditic strains of *Streptococcus viridans* had caused endocarditis were cut and studied by Rosenow and Coombs. Fourteen of these showed some microscopic evidence of invasion of the myocardium of the following character: In those hearts in which the animal succumbed soon after the injection of a large dose of the organism, masses of Gram-positive cocci were actually demonstrated within the smaller blood-vessels of the myocardium, and in some of these there was little or no inflammatory reaction. In other sections it was possible to discern that the cocci were undergoing destruction and phagocytosis by the endothelial cells of the small blood-vessels in which they became fixed; cocci, single, paired, and in short chains, were occasionally to be seen within the endothelial cells. In one or two instances the cocci were included within the endothelial cells. In one or two instances the cocci were included within a thrombus, which obliterated the lumen of the vessel. In none of the sections was there any evidence of profuse invasion of the myocardium by cocci.

In the majority of hearts, however, cocci were not seen in the myocardium, and the only evidence of invasion of that tissue lay in the presence of reactive changes varying in degree, but not transgressing above a certain maximum. These reactive phenomena expressed themselves primarily, in many cases exclusively, in changes in the vascular endothelium. The mildest evidence of intravascular irritation consists of a swelling of the endothelial cells, which appear to change from a flat to a cuboidal state. The next stage in their reaction is proliferative; changes of this type are particularly rife in the smallest arterioles and in the capillaries, also perhaps in perivascular lymph-vessels. A step beyond the proliferative process lies disintegration of the vascular endothelium, associated with thrombosis, and sometimes with break-up of the vessel wall—the result being the creation of an area having a small hyaline clot as its center, around which endothelial cells are irregularly arranged, constituting a zone separating the abnormal focus from the surrounding tissues. Apart from these various phases of endothelial activity—swelling, proliferation and degeneration—there was little sign of inflammatory reaction.

These phenomena are closely similar in several of their essential features to those witnessed in the following streptococcal infections: human rheumatic infection, experimental rheumatic infection, and experimental infection with *hemolytic* streptococci. The following fundamentals are common to all these infective processes: the myocardium is frequently invaded, the path of invasion lies through the myocardial blood-vessels, the endothelium of the blood-vessels plays a primary and predominant part in the defensive reaction, and the cocci are not found to have escaped in numbers beyond the vascular endothelial cells.

44. **Uncontrollable Vomiting of Pregnancy.**—In the first of the two cases described two injections of serum from a normal pregnant woman aided materially in the cure, the diuresis increasing at once afterward and the pregnancy proceeding undisturbed to term. In the second case both epinephrin and serotherapy failed to relieve, and labor had to be induced. The metabolic findings in these cases apparently indicate that the disturbances in the metabolism of nitrogen are the consequence of the starvation resulting from the uncontrollable vomiting. The greater these disturbances the graver the condition. The influence of treatment by alkalines is well founded although the alkali only modifies symptoms without removing the cause. When an alkali can be easily administered it is a useful adjuvant, but it is especially useful during the period of convalescence and return to normal conditions. The starvation seems to bring on an acid intoxication.

48 *Permanent Drainage of Ascitic Fluid into Subcutaneous Cellular Tissue. Perinoff.
49 Coagulation of Extravasated Blood in Joints after Trauma. L. Delrez.
50 *Operative Treatment of Gastric Crises of Tabes. P. Mauclaire.

48. **Permanent Autodrainage of Ascites.**—Perinoff discusses the various methods that have been applied to drain away automatically the ascitic fluid either by direct anastomosis with the portal vein, by diverting the fluid into the subcutaneous cellular tissue or by Ruotte's technic which sutures the saphena vein to the peritoneum. This latter technic has been applied to date in thirteen cases, mostly in Russia, with six successes. In cirrhosis of the liver with atrophy, the ascitic fluid induces phenomena suggesting anaphylaxis. Mauclaire's six patients all grew very weak and died almost at once after the ascites had been drained into the cellular tissue, with the exception of one in whom the ascites was of tuberculous origin. On the other hand, the outcome in cases of cirrhosis of syphilitic or alcoholic origin has been favorable. Perinoff has applied *autodrainage in three* cases with good results, the ascites accompanying cirrhosis of the liver of the type with simple venous hypertrophy, with no history of alcoholism. He used a silver tube, shaped like the tip of a catheter at one end, the other end slit and the two halves bent at right angles and placed to rest on the fascia after the tube had been introduced into the peritoneum.

This operation and drainage were subsidiary to omentopexy, which he regards as the important part of the operation. As it takes time, however, for collateral circulation to develop *after omentopexy*—the Talma operation—the tube drainage is provided as a temporary expedient. When the omentopexy has produced the desired conditions, then the tube drain can be taken out. The circumference of the abdomen in the two cases reported in detail subsided from 106 cm. to 96 and 86; the patients were young men of 23 and 17.

50. **Operative Treatment of Gastric Crises of Tabes.**—Mauclaire reviews the twelve different operative methods that have been applied in treatment of gastric crises, and reports his own experience in one case with Franke's technic, the tearing out of the intercostal nerves. He summarizes seventeen other cases from the literature, stating that the gastric crises were cured by the operation in seven cases; they recurred in eight cases sooner or later. In his own case the cure has been complete during the fifteen months to date. The patient was a woman of 64 who had had tabetic gastric crises during fifteen years. The fifth, sixth, seventh, eighth and ninth intercostal nerves were taken up in turn on a grooved sound and wound slowly on the sound until they tore; the peripheral stump was then cut. The fulgurating pains in arms and legs which the patient had had before the operation were not modified, but the gastric crises were abolished and she is now able to eat and digest approximately normally.

51 *Action of Digitalis on Alternating Rhythm. D. Danielopolu.
52 Frequency, Origin and Significance of the Phenomena of Extra Systoles in the Course of Heart Disease. V. Nefedoff.

51. **Action of Digitalis on Pulsus Alternans.**—Danielopolu concludes from his study of four cases that digitalis has both a retarding action on the myocardium and a retarding action on the length of the refractory period. According as one or the other of these elements predominates, the effect on the pulsus alternans is quite the reverse of that with the other. The retarding action seems to predominate generally, and consequently digitalis should at least be given a trial in these cases. The alternating rhythm and the phenomena indicating asystoly disappeared in his four cases while the heart was under the influence of the drug, but then returned in all but one case, in which the benefit was permanent.

62. **The Blood-Kidney Index in Kidney Disease.**—Bromberg expatiates on the importance of the information to be derived

from determination of the proportion of chlorids in the blood and in the urine. He states that in health the concentration in the blood is exactly one-half of the concentration in the urine, and this ratio of 1 to 2 is what he calls the hemo-renal index. He insists that the proportion in the urine or in the blood, taken separately, has not the least diagnostic significance, but comparison of the content in urine and the blood throws light on the functioning of the kidney. Determination of this index is the most practicable and simplest method of ascertaining the functional capacity of the kidneys. When the kidney is below par the elimination of chlorids is the first function to suffer: the nitrogenous substances never are retained while the inorganic salts continue to pass normally into the urine. A change in the hemo-renal index is the first sign of disturbance in the functioning of the kidney. It points to some disturbance long before any other clinical or laboratory sign or tests show anything wrong. As soon as the hemo-renal index becomes less than 1 to 2, some serious kidney disturbance in kidney functioning must be suspected, but the index will persist normal if one of the kidneys is sound. If the index drops below 1 to 1.5, no operation should be attempted on either kidney. If it is still lower than this, the prognosis is extremely grave. The chlorid content of the blood and of the urine is readily determined by comparing their electric conductivity, and Bromberg has devised a small electric apparatus which shows the resistance to the electric current of each of the fluids in turn. The current passes through the fluid by ionizing the atoms of the electrolytic salts; the stronger the concentration, the greater the conductibility. He gives an illustrated description of his simple little apparatus, saying that it requires only a few drops of either fluid; the findings can be read at once, and no previous experience or skill is required.

72 Apparatus for Excentric Extension of Stumps after Fracture of Leg. (Appareil pour le traitement des fractures de la jambe par embrochage et propulsion excentrique des fragments: Méthode de Lambret.) E. Quénu and P. Mathieu.

68. **Coxa Vara of Adolescents.**—Broca gives an illustrated description of coxa vara, its aspect and physical signs and the anatomic mechanism. The development of the deformity can be explained most plausibly by assuming some chronic pathologic process, and this was evident in a typical case reported. It commenced two years ago with slight pain in both hip joints occasionally, most marked on the left side. Little by little the lad had to give up bicycling and other sports as his hip joints tired easily and hurt him. He noticed that it was harder for him to stoop over and sit down; after eighteen months there was pain in the left knee. Pain in the knee is often merely a symptom of disease in the hip joint. The pains in hip joint and knee are not severe but persisting and aggravated by fatigue; the pain grows less, however, after the joints are warmed up by exercise. Notwithstanding the two years that have elapsed since the first sign of trouble, there is no displacement of the head of the femur, no swelling or suppuration, and the limb is inclined to flexion, abduction and outward rotation, contrary to what is observed with tuberculous coxitis. Roentgenoscopy confirms the assumption that the neck of the femur lies in an abnormally horizontal plane, and if the lad or girl is obliged to do hard work, lift heavy burdens or be on the feet much of the time, the deformity and pains continue to increase. On the other hand, if the patient is kept in bed with extension applied to the thigh, time will be gained for the parts to become stronger so that although once established deformity cannot be undone, yet there is no further progress and practically normal conditions are restored before long.

69. **Hot Air in Treatment of Suppurating Wounds.**—Roziès expatiates on the bactericidal action of hot air and its desiccating influence, aiding in cicatrization. He states that he has been much impressed with its efficacy in the fourteen cases of open sores in which he has applied the method. He uses a small portable air pump turned by a hand crank or a pump worked by a pedal, the air heated by an alcohol lamp. The sore heals over more rapidly and certainly than under other measures, and the scar seems to be less disfiguring, smoother and more flexible. The effect was particularly noticeable in suppurating wounds that had failed to heal under other measures, especially torpid leg ulcers and traumatic or operative superficial lesions. Of course deep bone processes are not influenced to such an extent.

73. **Operative Treatment of Crippled Knee.**—Brocq here concludes his long article on the treatment of vicious ankylosis of the knee, reviewing the various methods of treatment and the results obtained with them in various clinics. He reports a number of unpublished cases with illustrations of some of them and emphasizes the necessity for restoring the use of the limb as soon as possible to prevent the development of serious trophic trouble, which is usually progressive and is an imperative reason for early interference. When the angle of flexion is below 90 degrees, orthopedic resection is generally required. He says that there is no case on record above criticism which enables the assurance that a useful new joint can be made by the method of total grafts of a joint or even by interposition. The interval since has been too short for a conclusive judgment, but the results to date are encouraging to hope that certain adult patients may benefit by the attempt. Such operations are absolutely contraindicated in children on account of the inevitable injury of the cartilage. If any choice is legitimate as yet, Payr's method, interposing pedunculated flaps of fascia, seems the most promising. Brocq has applied this method in twelve cases. With operations hoping to restore the use of the joints, plastic operations on the muscles or tendons are generally necessary in addition. He advocates the use of an apparatus to measure and compare the knees and determine the degree of deformity and plan the method of procedure.

81 *Pyelitis in Children. L. Cheinisse.

December 10, No. 50, pp. 589-600

82 Improved Physiologic Solutions. (Nouvelles solutions physiologiques.) B. Schiassi.

81. **Pyelitis in Children.**—Cheinisse deplores the frequent neglect to examine the urine when infants and children develop fever of obscure origin. Few realize the frequency of suppuration in the urinary apparatus in young children; even cystitis is liable to be overlooked, to say nothing of pyelitis. In malarial countries where everything is ascribed to the malarial germ, colon bacillus cystitis or pyelitis is often treated with quinin alone; under it the general health grows progressively worse and no benefit from the drug in any way is apparent. Examination of the urine in such cases reveals

pus and colon bacilli The part played by kidney calculi in adults in the causation of pyelonephritis is taken by acute infectious diseases or gastro intestinal infectious processes in young children, especially as the kidneys in young children are particularly vulnerable to injury of all kinds The infants with pyelitis develop high fever and are extremely restless, children inclined to spasmophilia are liable to have convulsions, misleading the diagnostician to assume meningitis Anorexia, vomiting, diarrhea and mucous stools, rapid breathing, and a yellowish, even jaundiced tint and distressed expression show that the child is very sick There may be one or more chills, otherwise chills are rare in infants, even in malaria The child grows rapidly thin, the high continuous fever at first becomes remittent or intermittent, and typhoid may be erroneously diagnosed In older children the clinical picture may not be so severe, pallor, anorexia and periods of pyrexia alternating with non febrile periods Bosanquet has reported the case of a boy of over 2 who had periods of pyrexia regularly every four or five days, in a girl of 6 the periods of pyrexia came on about the tenth or fifteenth day and in the intervals she seemed in normal health

There are no local signs in the majority of cases, especially in infants Left untreated, the pyelitis is liable to become chronic while as a rule it is amenable to proper treatment As the cause of the pyelitis is probably some obstruction to the flow of urine in the kidney pelvis, and as this in young children can usually be remedied by forcing the urine, the aim in treatment should be to induce copious secretion of urine to flush out the kidney pelvis by drinking large quantities of fluids All agree as to the importance of this, but opinions differ as to the wisdom of giving drugs to sterilize the urine Lenhartz denounces them at any age, saying that the best treatment is to have the patient drink three or four times a day a pint of hot infusion of linden flowers which mechanically clears out the urinary apparatus, keeping this up for weeks and even for months Goppert and Langstein recommend the use of hexamethylenamin and salol alternately. The former gives children from 2 to 9 months old, 0 05 gm of salol five to eight times a day, and children up to 2 years, 0 2 gm five or eight times a day Langstein gives, even to infants, from 0 1 to 0 3 gm four times a day and 0 5 for older children Still advocates potassium or sodium citrate enough to keep the urine alkaline day and night for a week or ten days at least

89 **Functional Disturbances in Neighboring Organs after Operation for Goiter.**—Pampel gives a detailed study of the anatomy of the region and reviews the experiences since 1900 with 182 patients who were operated on for goiter, the list includes only three with exophthalmic goiter Severe postoperative disturbances in swallowing are extremely rare They are connected with paralysis of the recurrent nerve, and when this occurs the patient must be fed exclusively through a tube and with the foot of the bed raised to keep the throat region low so that no fluids or solids will get into the air passages Collaterals develop rapidly and by the end of a week the patient is able to swallow approximately normally, Of the nine patients with postoperative unilateral recurrent paralysis, one has been lost track of, one has completely recovered, two are still in the same condition and in two the condition has grown worse, but speech is not impaired in one, in the other the paralyzed vocal cord has atrophied Postoperative laryngeal trouble occurred in thirty two instances, that is, in 17 58 per cent of the total material, but in all but the above nine the edema, hemorrhage or paresis proved briefly transient.

91 **Incarceration of Undescended Testicle.**—The patient was a man of 24 and the testicle was functionally destroyed by the seven hours of interference with its circulation The shock and collapse were extreme as usual in these cases from the intense pain

93 **Vascular Changes in the Appendix**—Von Redwitz gives four colored plates to illustrate his long article describing the conditions found in the vessels in an inflamed appendix Periodical colic like pain with appendicitis is probably the result of changes in the arteries, causing pain like that of intermittent claudication and from the same mechanism The pain ascribed to a movable colon may be due to the same cause He summarizes 132 cases and gives several pages of bibliography.

96 **Blood in Joints**—Mankiewicz refers to the extravasation of blood in the joints of hemophiliacs and discusses the three stages of the trouble, the accumulation of blood, the consequent irritation of the joint and the resulting crippling of the joint He gives roentgenograms of the knee in some cases with a history of hemophilia; the knees show traces of the panarthritis, the joints having become inflamed from the presence of the blood The changes seem to be quite characteristic, and roentgenoscopy may thus disclose an unsuspected tendency to hemophilia in patients with joint trouble The joint in this second stage is swollen and feels hot, while the x ray shows the bones atrophied and deficient in lime The surfaces of the bones and cartilage are rough and there are small patches of darker shadow at the capsule with rarefication of the condyle tissue, especially the internal The epiphysis line is remarkably distinct for adult males but it is jagged, the quadriceps is atrophied The roentgen findings resemble those with chronic deforming arthritis, the permeability of the bones for the rays show the lack of the normal proportion of lime This transparency of the bones may be pronounced even in the shoulders and feet

97 **Test for Gastric Secretion**—Skaller's method aims to supplement the findings with the test breakfast, recording conditions as to the course of the secreting functions, showing progress under treatment The patient swallows a duodenal tube with several openings It is kept from passing through into the duodenum by having the tube too short to pass the pylorus Patients soon learn to swallow this narrow tube—the lumen is not over 2 mm —and it causes no discomfort nor

tendency to vomit even when left for hours. The patient swallows the tube, fasting, and then takes 200 gm. of Liebig's meat extract, at room temperature. Every five minutes 3 or 15 c.c. of stomach content is aspirated through the tube and the acidity titrated. To ensure mixing of the stomach contents, air is forced in through the tube each time before siphoning out the contents. The proportion of acid found is recorded on a chart, and an objective oversight is thus obtained of conditions in regard to gastric secretion Some of the curves given show the fluctuating course of the acidity, so that the findings at different times within the hour are thus seen to vary within a wide range.

98. **Splenectomy for Pernicious Anemia.**—The remarkable improvement that followed splenectomy in the case reported suggests that the spleen must be a much more important factor in pernicious anemia than hitherto suspected. It seems to acquire a very destructive action on the red blood corpuscles while at the same time exerting an influence on the bone marrow, checking the production of new red corpuscles This pathologic disturbance in the functioning of the spleen is evidently the result of the myeloid changes in the spleen which have hitherto been comparatively disregarded. Removal of the spleen therefore does not remove the cause of the disease, but it does away with the source of several of the most serious elements in the disease The bone-marrow may recuperate completely in mild cases when this disturbing element drops out, and even if it is unable to do this, the general condition improves when the red corpuscles which are produced cease to be destroyed in such wholesale numbers when the spleen is gone. His patient was a woman of 34 with a history of well treated syphilis four years before. The pernicious anemia was in a threatening stage, hemoglobin 15 per cent. and only slight benefit was realized from repeated intragluteal injection of 20 or 25 c.c. of defibrinated blood. The splenectomy took only twenty minutes; in future he will ligate the different arteries preliminary to removing the spleen as this would save a lot of blood. Fully 150 c.c. of blood flowed from the spleen after its removal. The patient felt better by evening and the improvement was pronounced the next day and later. By the fifth week the hemoglobin was 50 per cent. and the reds numbered two and a half millions. There was no further edema, jaundice or urobilinuria. The seventh week the progress toward recovery seemed to stop and the hemoglobin dropped to 42 but increased to 43 under repeated injections of blood. The patient is now taking fresh beef spleen. She is up and about and cheerful to date, in marked contrast to her desperate condition before the splenectomy.

109. **Treatment of Faint, Shock and Collapse.**—Grober says that the first thing is to feel of the pulse. If the symptoms suggest lack of blood in the head, the foot of the bed should be raised or the lower part of the body can be lifted. The easiest way to arouse the patient from his lethargy in case of severe syncope is with a towel wet with cold water with which the skin is slapped at various points, thighs, chest, back and arms, avoiding carefully the abdomen. At the same time the legs and the soles are rubbed vigorously with a dry cloth or hard brush As the face loses its livid aspect, the lids and lips move, the first complaint is generally of the cold, and the skin still feels cold with a clammy sweat. Then the patient is warmly covered, hot bottles are placed in the bed, and he is given hot drinks, brandy and water, hot bouillon or meat extract As he recovers, the room is kept quiet and darkened, with someone to watch over the pulse and respiration, keep the patient horizontal, and keep out the anxious family A moderately severe syncope of this kind is liable to be brought on by the vitiation of the air in crowds and by fright and horror. The anemic and those with heart and lung disease succumb more readily, and the condition is more refractory to treatment. The physician must act promptly and vigorously in such cases; long hesitation may be disastrous The severer forms may prove directly fatal. Grober emphasizes the danger in such cases from constriction by clothing, tight collar or belt. Sometimes a knife, with the edge turned away from the patient, cutting the tight bands or garters, may work wonders Stimulation of the mucosa with vinegar, ammonia or the like, or mechanical stimulation of the nasal mucosa with a feather or spear of grass may prove useful, especially if the feather is scorched to add the pungent odor. An additional measure is to bandage the limbs from the periphery upward to induce autotransfusion. The pulse often grows very much better. Stimulating enemas were formerly much used and may prove of some assistance, 30 or 75 c.c. of brandy in two or three times this amount of hot water. Some of the above measures should be applied with energy but not too long, and if the pallor, small pulse and shallow breathing keep up, stimulants for the heart are necessary. He has seldom witnessed any benefit from epinephrin in shock and collapse, and thinks it is more rational to give digitalis instead.

Respiration can be promoted by pressing on the costal arch region to pump more air out and in, or maneuvers for artificial respiration may be systematically applied. A few minutes may restore the respiration to normal conditions but sometimes it must be kept up for hours, with an assistant for each arm, changing places every seven minutes to pump the other arm. The tempo should not be more than 15 or 20 to the minute. Slapping the heart region with the flat hand, about seventy times a minute, is preferable to rougher manipulations; in the very lean the heart may be directly grasped upward through the diaphragm if the abdominal wall is much relaxed, but it must not be forgotten that the left lobe of the liver is acted on at the same time. In the agitation of shock, notwithstanding the weakness of the pulse and respiration, sedatives may be needed along with the stimulants for the heart The aspiration of vomit must be prevented by keeping the head turned to the side, and wiping out the mouth and throat with the finger wrapped in gauze or with a gauze sponge. The patient must never be allowed to sit up in the first few hours after a severe syncope; the headache and insomnia are best combated by lowering the head. The dangers of collapse and shock must not be aggravated by any further loss of blood, consequently no operation should be done until the centers in the medulla oblongata have resumed their functioning. Patients who have severe syncope, shock or collapse should be kept under supervision for some time afterward to protect them against relapses and further injury of organs

112. **Protecting Influence of Protein Diet Against Tuberculosis.**—The experimental research reported showed that young pigs fed systematically with casein were much more resistant to inoculation of tubercle bacilli than others of the same litter fed with carbohydrates or fats

113. **Decortication of the Lung in Treatment of Tuberculous Cavity.**—Mayer says that when conditions prevent injection of a gas to effectually compress the lung, about equally

good results may be obtained by loosening the lung from outside and inside the pleura, directly over the cavity. The lung may collapse immediately when the pleura is detached, and stay collapsed.

127. **Tetanus.**—Permin's account of his experimental and clinical research on tetanus fills seventy-one pages. It includes also a survey of the results of treatment of tetanus in various lands, especially in Denmark, before and after the production of tetanus antitoxin. In the 388 cases reported in Denmark, 72.8 per cent. of the antitoxin-treated patients died when the incubation period had been less than ten days, and 94.7 per cent. of the ninety-four patients to whom serotherapy had not been applied. The proportion of total recoveries has risen since serotherapy came in from 21.1 to 42.3 per cent. of 199 and 189 cases, respectively. But he insists that great improvement is still possible with perfected technic based on the knowledge that the antitoxin cannot act on the toxin already anchored in the cells. It neutralizes only the toxin still circulating in the blood and the fresh toxin as it is poured into the blood. The most promising method is to proceed the moment the tetanus is diagnosed to draw 16 or 33 c.c. of cerebrospinal fluid by lumbar puncture and inject 100 or 200 antitoxin units. With extreme opisthotonos slight general anesthesia may be required. The foot of the bed should be raised to send the serum up the spinal canal. If lumbar puncture is impracticable, he makes an intramuscular injection of the same amount. Then the wound is examined and foreign particles removed, the opening enlarged, and the cavity rinsed with some antiseptic and tamponed with silver nitrate gauze, providing for ample drainage. The intraspinal or intramuscular injection is repeated each day for five or six days and then every third day until marked improvement is observed.

The serotherapy by no means does away with the necessity for chloral or morphin. The dosage must be proportional to the age of the patient and the severity of the tetanus. Some clinicians give very large doses of chloral, but Permin thinks it is wiser to keep below the maximum dose and supplement the chloral with morphin, keeping the patient in a quiet, darkened room. It is of the utmost importance that the patient should get adequate nourishment as the resisting powers depend to such an extent on this. Fluid foods are best and with extreme lockjaw it may be necessary to pull a couple of teeth to permit the introduction of a rubber tube through which fluid nourishment can be poured into the mouth. If there is spasmodic contraction of the muscles of swallowing, a dose of chloral half an hour beforehand will help to relax the spasm. If the paroxysms recur with threatening frequency or severity, all should be in readiness to give a few whiffs of ether or chloroform. Intraspinal injection is urgently required in all cases of local tetanus; it acts here the same as if injected into the nerve while the technic is much simpler and easier.

128. **Vaccine Therapy.**—Wolfsohn discusses the various affections in which vaccine therapy seems promising and reviews the results realized to date. He has seven years' experience of the method. All clinicians seem to agree that properly applied vaccine therapy is harmless. Any aggravation of the condition that may occur later probably would have occurred the same without the vaccine therapy. The danger of anaphylaxis seems to be negligibly slight; at least. to date nothing has been known of a threatening character in this line. Even the greatest skeptics must be convinced of the beneficial results in certain affections. Still better results may be anticipated when the vaccine therapy is supplemented by other therapeutic methods, especially chemotherapy, and when the desired clinical reaction is realized with the least dangers by utilizing vaccines made with the least possible injury of the antigen elements. He has applied vaccine therapy to thirty-four acne patients, and nine were not influenced in the least; nine were temporarily improved, and sixteen were completely cured of their long rebellious acne. No benefit was apparent in his twelve cases of postoperative osteomyelitis fistula, nor in six of mastitis, but his success in six cases of furunculosis in infants justifies further trials with small doses. Vaccine therapy to date has been applied in about 2,000 cases of furunculosis in adults, but the published records do not state whether the trouble was old and chronic in all the cases, while this alone calls for vaccine therapy. In his thirty-two cases the furunculosis had lasted from two to twenty years, and twelve of the patients were completely and twelve others partly cured. In eight others no influence from persevering vaccine therapy was apparent. The cure has persisted from one to three years to date. A polyvalent vaccine often proved effectual but autogenous vaccines were more reliable.

In only three of his fourteen cases of chronic eczema was a cure realized, and nine were entirely uninfluenced. His success surpassed all expectations in six cases of obstinate sinusitis in the accessory cavities of the nose. General streptococcus infection is less promising for vaccine therapy, and the treatment failed completely in his eight cases of erysipelas of the face and in four at other points, but in two cases of erysipelas of the arm distinct benefit was apparent. Acute streptococcus affections contra-indicate vaccine therapy, but it may help in the subacute and chronic cases, especially with scarlatinal complications and migrating erysipelas. Vaccine therapy is especially effectual in gonorrheal arthritis, most so when associated with means to induce stasis hyperemia. Good results from vaccine therapy have also been reported with epididymitis and, less constantly, with pyosalpinx. Failures have been reported in all forms of gonorrheal catarrhal mucous membrane affections, such as urethritis, endometritis and conjunctivitis. Great caution is necessary with general gonorrhea, especially when there is endocarditis. Stock vaccines are of no use with colon bacilli, and vaccine therapy in general is of use only in the chronic forms and in these only, as a rule, when the urinary apparatus is involved and only when there is a pronounced reaction. In chronic colon bacillus cystitis and pyelitis a vaccine in combination with other measures may hasten the cure but the urine is not freed from the bacilli in every instance. Vaccine therapy is promising also in certain diseases among cattle, such as contagious vaginal catarrh, and in strangles in horses.

131. **Ulcerative Colitis.**—Schmidt states that fifteen of his thirty patients with severe ulcerative colitis were treated with internal measures alone, and eight were cured and one improved. Among the fifteen operative cases he records only two cures and seven improvements. He tabulates thirty cases from the literature to compare with them, and comments on the severe complications liable with the colitis, thrombosis, polyarthritis, exophthalmic goiter, pneumonia, multiple neuritis and embolism in ten of the cases, all evidently of septic

origin. No permanent cure was ever realized from medicines by the mouth although calomel and ipecac have helped. Better results were attained with drugs by the rectum, given with acacia in weak concentration to refrain from irritating, supplemented by external heat and other symptomatic measures.

133. **Local Retention of Iodin in Segregated Region.**—Salomon refers to Bier's method of enhancing the therapeutic action of stasis hyperemia in surgical tuberculosis by giving at the same time potassium iodid internally. Salomon investigated conditions afterward in twelve persons and in rabbits given similar treatment; the data all confirm the remarkable retention of the iodid in the edema fluid and tissues in the segregated limb. The retained iodin is not eliminated when the constricting band is removed but remains stored up in the tissues for a time. The practical importance is obvious of this retention of therapeutic substances under the influence of stasis hyperemia. Others have reported similar storing up of salicylic acid under the same conditions. We are able thus to supply the healing drug almost directly to the diseased tissues and in the strongest concentration possible. We can inject a drug directly into the focus and hold it there by this means without fear of general toxic action. In one of the eight cases reported a chronic rheumatic affection of the hand became very much swollen and worse under the iodid and constriction of the shoulder. After subsidence of these phenomena, however, the condition was found materially modified for the better.

134. **Magnet in Prophylaxis and Treatment of Peritoneal Adhesions.**—To fill the gastro-intestinal tract with a suspension of reduced iron or other form of iron and then move parts of the tract around at will by applying a very large magnet to the abdominal wall, is Payr's ingenious idea. He gives a number of illustrations to show the way in which the iron-filled intestine rises up in a peak in response to the attraction of the magnet, or several loops of intestine crowd together at the point nearest the magnet. The movements of the loops can be seen through the abdominal wall as it bulges above them and they can be inspected still closer with the Roentgen screen. He has been experimenting with various forms of iron for the purpose, and various applications of the method, finding that artificially induced adhesions could be broken up by the force of the magnet. One of his illustrations shows how the fine particles of iron in the bowel under the influence of the magnet arrange themselves in the curved lines familiar in the study of physics as the magnetic lines of force. Payr states that the most scrupulous macroscopic and histologic study of the intestines afterward failed to show the slightest injury from the procedure, not even a trace of capillary hemorrhages in the intestines where they had been drawn up and long held against the abdominal wall. The method was applied also to two thin women, one of whom had symptoms suggesting trouble from adhesions in the region of the sigmoid flexure. The application of the magnet to this point, after an enema of the iron suspension, caused distinct local pain. The magnet applied elsewhere to either women was not felt subjectively in any way. He used a magnet like those made to extract metal particles from the eye, but this is awkward for the purpose, and he is now trying a smaller magnet, with a force of about 75 kgm., mounted on a standard with counterweight, convenient to apply to the erect or reclining patient. He gives a list of ten different indications for which the method seems promising, including the stimulation of peristalsis when there is a tendency to postoperative paresis of the bowel, reduction of torsion and invagination and correction of sagging of the bowel, enteroptosis. By varying the amount of iron, the force of the magnet and its distance, the procedure can be adapted to individual dosage, and the movement can be produced in any desired direction under direct visual control with the Roentgen rays. He fed some of the rabbits and guinea-pigs with 1 or 2 gm. of ferrous oxid daily and their health did not seem to be affected in the least. Others were given the iron in a flour gruel or suspended in agar-agar. In the clinic it might be better to give the iron in a capsule. Both reduced iron and ferrous oxid can apparently be taken with impunity as both are insoluble in weakly alkaline mediums, and nothing to suggest injury was discovered in the experimental research and clinical experiences reported.

138. **Roentgen Treatment of Tuberculous Lymph-Nodes in the Neck.**—Fritsch has applied this treatment in thirty-three cases during the course of a year, the ages of the patients between 7 and 30; eight are entirely cured and eight much improved. Accompanying tuberculous lesions elsewhere reduce the prospects of success. In four cases a hard lump was left which he cut out, and he extols the advantages of thus combining treatments. The roentgenotherapy is liable to prove effectual without leaving a disfiguring scar and without the necessity for operating under general anesthesia. It can be applied also without interfering with the patient's occupation, but a six months' course is generally necessary. He followed Kienböck's technic in every case.

139. **Serotherapy in Scarlet Fever.**—Koch reports an additional series of 28 cases, bringing the total to 40 in which scarlet fever patients were treated with serum from others convalescing from the disease. In all the scarlet fever was of a very severe type. Of the total 263 cases of scarlet fever in the last year, 6.5 per cent. of the children developed nephritis and 1.1 per cent. died. Of the 12 treated with normal human serum 16.7 per cent. developed nephritis and 8.3 per cent. died, while of the 28 treated with serum from convalescents, none developed nephritis and only one already moribund patient died. The effect of this form of serotherapy was most striking in the cases of severe toxic scarlet fever without complications; in fact the serotherapy does not seem to act on complications. The curves from a number of cases are given to illustrate the prompt and beneficial action of serotherapy in this form. The communication issues from the public hospital at Frankfurt a.M.

140. **New Bases for Dietetics.**—Funk refers to the recent discoveries in regard to the importance of certain minute quantities of certain substances in the food the lack of which entails disturbances of which beriberi is an extreme type. (Discussed editorially in THE JOURNAL, 1913, lx, 1543.) These special substances may be destroyed in the cooking, by overheating (milk), by taking out in boiling, by carrying desiccation too far (especially in feed for cattle), and by discarding the outer covering of grains, especially rice, corn, wheat and rye. A loss of appetite and repugnance for food he regards as an early sign that the system is suffering from lack of these special substances or vitamines, as they have been named. The diet should at once be modified to supply variety and sufficient amounts of the vitamines, a digestible, light mixed

good results may be obtained by loosening the lung from outside and inside the pleura, directly over the cavity. The lung may collapse immediately when the pleura is detached, and stay collapsed.

127. **Tetanus.**—Permin's account of his experimental and clinical research on tetanus fills seventy-one pages. It includes also a survey of the results of treatment of tetanus in various lands, especially in Denmark, before and after the production of tetanus antitoxin. In the 388 cases reported in Denmark, 72.8 per cent. of the antitoxin-treated patients died when the incubation period had been less than ten days, and 94.7 per cent. of the ninety-four patients to whom serotherapy had not been applied. The proportion of total recoveries has risen since serotherapy came in from 21.1 to 42.3 per cent. of 199 and 189 cases, respectively. But he insists that great improvement is still possible with perfected technic based on the knowledge that the antitoxin cannot act on the toxin already anchored in the cells. It neutralizes only the toxin still circulating in the blood and the fresh toxin as it is poured into the blood. The most promising method is to proceed the moment the tetanus is diagnosed to draw 16 or 33 c.c. of cerebrospinal fluid by lumbar puncture and inject 100 or 200 antitoxin units. With extreme opisthotonos slight general anesthesia may be required. The foot of the bed should be raised to send the serum up the spinal canal. If lumbar puncture is impracticable, he makes an intramuscular injection of the same amount. Then the wound is examined and foreign particles removed, the opening enlarged, and the cavity rinsed with some antiseptic and tamponed with silver nitrate gauze, providing for ample drainage. The intraspinal or intramuscular injection is repeated each day for five or six days and then every third day until marked improvement is observed.

The serotherapy by no means does away with the necessity for chloral or morphin. The dosage must be proportional to the age of the patient and the severity of the tetanus. Some clinicians give very large doses of chloral, but Permin thinks it is wiser to keep below the maximum dose and supplement the chloral with morphin, keeping the patient in a quiet, darkened room. It is of the utmost importance that the patient should get adequate nourishment as the resisting powers depend to such an extent on this. Fluid foods are best and with extreme lockjaw it may be necessary to pull a couple of teeth to permit the introduction of a rubber tube through which fluid nourishment can be poured into the mouth. If there is spasmodic contraction of the muscles of swallowing, a dose of chloral half an hour beforehand will help to relax the spasm. If the paroxysms recur with threatening frequency or severity, all should be in readiness to give a few whiffs of ether or chloroform. Intraspinal injection is urgently required in all cases of local tetanus; it acts here the same as if injected into the nerve while the technic is much simpler and easier.

128. **Vaccine Therapy.**—Wolfsohn discusses the various affections in which vaccine therapy seems promising and reviews the results realized to date. He has seven years' experience of the method. All clinicians seem to agree that properly applied vaccine therapy is harmless. Any aggravation of the condition that may occur later probably would have occurred the same without the vaccine therapy. The danger of anaphylaxis seems to be negligibly slight; at least. to date nothing has been known of a threatening character in this line. Even the greatest skeptics must be convinced of the beneficial results in certain affections. Still better results may be anticipated when the vaccine therapy is supplemented by other therapeutic methods, especially chemotherapy, and when the desired clinical reaction is realized with the least dangers by utilizing vaccines made with the least possible injury of the antigen elements. He has applied vaccine therapy to thirty-four acne patients, and nine were not influenced in the least; nine were temporarily improved, and sixteen were completely cured of their long rebellious acne. No benefit was apparent in his twelve cases of postoperative osteomyelitis fistula, nor in six of mastitis, but his success in six cases of furunculosis in infants justifies further trials with small doses. Vaccine therapy to date has been applied in about 2,000 cases of furunculosis in adults, but the published records do not state whether the trouble was old and chronic in all the cases, while this alone calls for vaccine therapy. The curves from a number of cases are given to illustrate the prompt and beneficial action of serotherapy in this form. The communication issues from the public hospital at Frankfurt a.M.

140. **New Bases for Dietetics.**—Funk refers to the recent discoveries in regard to the importance of certain minute quantities of certain substances in the food the lack of which entails disturbances of which beriberi is an extreme type. (Discussed editorially in THE JOURNAL, 1913, lx, 1543.) These special substances may be destroyed in the cooking, by overheating (milk), by laking out in boiling, by carrying desiccation too far (especially in feed for cattle), and by discarding the outer covering of grains, especially rice, corn, wheat and rye. A loss of appetite and repugnance for food he regards as an early sign that the system is suffering from lack of these special substances or vitamines, as they have been named. The diet should at once be modified to supply variety and sufficient amounts of the vitamines, a digestible, light mixed

diet including fresh fruit, vegetables, potatoes, meat, milk and butter, remembering that fruit and vegetables lose their vitamines by drying; they are also lost if the water in which they are boiled is thrown away. He adds a list of foods rich in vitamines, egg yolk, whole wheat and whole rye bread, moderately roasted meat, fresh vegetables and vegetable soups, fresh yeast, and cod liver oil. The discovery of the vitamines throws light on the superiority of breast milk for infants and on the injurious effect of too long or too high heating of cow's milk. The nursing woman must have a diet rich in vitamines; possibly cooked yeast might serve to promote production of milk in women as it has proved useful in dairies. In any event he thinks it is worth a trial. In conclusion he says that the question of the origin of pellagra is in the same stage now as that of beriberi ten years ago. One thing is certain, he declares, namely, that there is no endemic pellagra outside of corn-consuming districts. The drying of the corn may be responsible for the loss of its vitamines; and he thinks that corn is scarcely suitable for food At least it should be eaten only with articles particularly rich in vitamines, and the whole grain should be used.

142. **Mechanical Aid in Treatment of Tabes.**—Baeyer gives an illustration of a spring splint which he buckles to the leg and thigh with a metal sole. He has found it of great service in reeducating tabetics to walk. The splint enables the patient to perceive the position of the joints and the state of contraction of the muscles, as it checks mechanically both the active and passive movements of the limb and thus the patient gets much better control over the limb The benefit was constant and pronounced in all the cases in which he has applied the splint It can be used where a course of systematic training is impracticable for any reason or as accessory to these exercises

147. **Treatment of Albuminuria and Nephritis.**—Strauss remarks that the progress in this line in the last twenty years has been mainly by determining and enlarging the principles on which the older methods of treatment depended. He regards it as great progress that attention has been diverted more to the constitutional form of albuminuria during, preceding and following puberty. Changes in the distribution of the blood-supply are mainly responsible for this orthostatic albuminuria and lordosis albuminuria. The recently acquired knowledge in this line has brought progress in that more active measures are applied *now:* change of climate to the mountains or the sea, extra nourishing food and physical measures to render the patient more robust. Especial care must be exercised to refrain from getting chilled. In regard to diet he says that in all his experience he has never encountered but one case in which there seemed to be injury from eggs in nephritis. The preparation of the food, especially the way meat and vegetables are cooked, is very important. He says in conclusion that decapsulation of the kidney can be recommended only in cases of long persisting extreme oliguria accompanied by uremic or suburemic phenomena, especially in acute nephritis; less in the chronic form. He recently witnessed remarkable benefit from decapsulation in a case of scarlet fever. The physician now, he reiterates, cannot be content with the old-fashioned way of treating nephritis, treating all patients on the same basis, with a certain monotony. He must differentiate the special points to be aimed at, with his therapeutic measures in each individual case

148. **Anaphylaxis after Fibrolysin.**—The fibrolysin was injected in treatment of pain in the region suggesting possible peritoneal adhesions, relics of an old gall-stone affection. After the tenth injection an extensive eruption, suggesting measles, suddenly developed. The patient was a woman of 64. The injections were suspended but were resumed three years later on return of the symptoms and vibratory massage was applied to the gall-bladder. After the third injection the patient seemed to be suddenly suffocating for a time, and a fourth injection was followed by a chill and fever with much distress and pain. The pains subsided after twenty-four hours and, a week later 2 c.c. of fibrolysin was injected anew, and again suffocation and distress followed. The phenomena observed can be explained only, he thinks, by accepting anaphylaxis. The fibrolysin was kept up, notwithstanding, to complete the course, and the beneficial effect was permanent.

149. **Iodin Sterilization of the Throat after Diphtheria.**—Abel thinks that little is accomplished by the ordinary methods of gargling the throat, etc. The only way to thoroughly sterilize the throat, he says, is in the form of vapor. Nothing else finds its way so infallibly as vapors into all crevices, and he advocates iodin for the purpose, generating nascent iodin by heating iodoform in a flask with two bent glass tubes through the rubber stopper, one tube connected with a rubber bulb, the other with a narrow rubber tube. When the flask fills up with the iodin fumes as the iodoform is heated over an alcohol lamp, he blows the fumes through the nostrils and into the pharynx, repeating this twice a day for three days He has thus treated eighty-nine patients with diphtheria bacilli lingering in their throats longer than three weeks after recovery from diphtheria. Of the total eighty-nine the bacilli had disappeared in 47 per cent. after a three days' course; 31.5 per cent. required two courses and 20 per cent three courses. Two patients proved absolutely refractory, no result from the treatment being apparent. Reexamination later in a number of the cases confirmed the thorough eradication of the bacilli.

151. **Fatality after Local Anesthesia.**—Proskauer reports that a man of 47 died suddenly after 20 c.c of a 2 per cent. solution of alypin had been injected into the bladder The only thing that could be found to explain this fatality was an extensive tuberculous process in the right adrenal. He theorizes to explain the mechanism of this fatality and cites three cases from the literature in which death followed at once after local anesthesia with cocain or novocain and in both cases necropsy revealed a tumor in the chromaffin substance.

152 Discussed editorially on page 47.

159 Developments [illegible] Form von Entwicklungsst [illegible] A Heigel.

156. **Etiology of Duodenal Ulcer.**—Scagliosi discusses the various theories as to the origin of duodenal ulcer, and gives detailed histologic descriptions of specimens from several cases of his own. He concludes that self-digestion of the wall of the stomach or duodenum cannot take place so long as circulation and nutrition are normal. The chief cause is to be found in pressure on the blood-vessels by swollen Brunner's glands and accessory pancreatic cells. This disturbes nutrition and allows autodigestion to take place. Ulcer is generally secondary to duodenal adenoma.

157. **Plastic Drainage of Ascites.**—Schepelmann describes the case of a 65-year-old man with pronounced ascites from cir-

rhosis of the liver. There was also marked arteriosclerosis. A varicose vein the size of a lead pencil, hardened in formaldehyd solution was sewed into the peritoneum and for six and one-half weeks the fluid was conducted into the subcutaneous tissue where it manifested itself by doughy edema of the abdominal wall. Absorption took place from here through the blood and lymph channels. At the end of that time there was partial occlusion of the vein by fibrin. Therefore he recommends the use of larger vessels, a varicose vein as large as the thumb, for instance, or the aorta of a calf. Experimental work can be done on the human subject as there is no irritation and consequently no proliferation of connective tissue as there would be from the use of tubes of metal, rubber or glass.

164 *Ultimate Effect of Tonsillectomy. S. Tenzer.
165 *Permanent Therapeutic Pneumothorax. E. Rochelt.

164. **Effect of Tonsillectomy.**—Tenzer has been reexamining lately a number of children whose tonsils were removed over two years before, and states that there is nothing to indicate any deleterious influence from the tonsillectomy. On the contrary, the children bloomed into good health after the operation and the effect in abolishing the recurring attacks of acute tonsillitis was ideal.

165. **Permanent Therapeutic Pneumothorax.**—Rochelt introduces a trocar with a valve and hermetically closing cap which he introduces as for an ordinary artificial pneumothorax, but leaves the trocar permanently in place. This permits the refilling of the space with the gas as often as desired, without inconvenience to the patient. For this reason ordinary air can be injected and a gas, like nitrogen, is not needed. A special advantage of this retention trocar is that the air is more rapidly absorbed and consequently the compression of the lung fluctuates at times just enough to maintain the elasticity of the lung tissue. Another advantage is that the insufflations as needed do not require any special skill beyond insuring asepsis in the procedure.

178 *Modern Treatment of Osteomalacia. F. Schnell.
179 Operative Treatment of Incontinence of Urine and Extensive Genital Prolapse. P. Steffeck.

171. **Influence of Obstetric Impression of the Skull.**—Gfroerer states that at the Würzburg maternity obstetric impression of the skull is treated only as symptoms arise. In all the cases that came to necropsy other injuries were found more than sufficient to explain the fatality without incriminating the depression in the skull. Even such simple procedures as manipulating the skull to make it spring back into place or drawing it up with a corkscrew are liable to prove serious. In seven cases of obstetric impression in his service the pelvis had been too small to permit normal delivery and the injuries proved fatal. In seventeen other cases the pelvis was contracted but not enough to do serious injury and the children were born in good condition. Five died from intercurrent disease about a year later; the others have developed normally and no deleterious influence has been observed on the growth of the body or mind, not even in the cases of instrumental delivery.

178. **Treatment of Osteomalacia.**—Schnell reviews 334 cases of osteomalacia he has found recorded in the last fifteen years. All methods of treatment have had their successes and their failures, but castration seems to have been most constantly successful. Recurrence is known in only seven cases of the 105 in which the osteomalacia was combated by castration. No other method of treatment can compete with this record which has now a twenty-five-year history.

184. **Sign of Neurasthenia.**—Pancrazio states that for years Ancona and he have noticed that when they ask a patient to show them his tongue if he puts out his tongue in such a way that the back of the tongue and the throat are visible, further examination will almost inevitably reveal other signs of neurasthenia or a neurotic predisposition. Pancrazio calls it an actually specific objective neuropathologic sign, and explains it by the habit of the nervously disposed to examine their own tongues. They look at their tongue so often, and at their throat that the tongue becomes trained in submitting to examination and exposes itself readily and completely, while persons who do not take this morbid interest in examining their physical condition are unable to show the back of the tongue and the throat, as a rule, when told to put out the tongue.

187. **Epinephrin in the Kidney Complications of Scarlet Fever.**—Paoloantonio states that he injected epinephrin to arrest hematuria in a child of 5, at the fifteenth day of scarlet fever, with signs of nephritis and edema. The urine contained ten per thousand albumin and numerous tube-casts while the amount of urine was constantly declining. Suddenly the fever ran higher and blood appeared in the urine, the output of urine growing still scantier. He then injected the epinephrin to arrest the bleeding and also perhaps stimulate the heart action which seemed weak. The third day he gave the epinephrin by the mouth as he saw that not only the blood had disappeared, but also the albumin had dropped to one-half the previous proportion; the edema was absorbed, the diuresis increased and the general condition notably improved. By the tenth day the urine seemed to be entirely normal. Encouraged by this success he applied the epinephrin also in thirty other cases of kidney trouble in scarlet fever, and found it equally effectual in all. By the second day the

condition showed marked improvement and the danger of uremia seemed to be averted. He gave from ten to twenty drops a day, by the mouth, of the usual one per thousand solution except where the urgency of the case called for subcutaneous injection at first.

193 *Human Serum Therapy in Pulmonary Tuberculosis. (Di alcuni saggi di sieroterapia antitubercolare interumana in rapporto anche ad arresto di emottisi.) A. Miliani.
194 Roentgen Therapy in Lupus. D. G. Scaduto.

192. **Therapeutic Pneumothorax.**—Angelini states that in twelve of the nineteen patients treated by intrathoracic injection of a gas, anatomic conditions facilitated the pneumothorax and at one stroke the symptoms subsided. This immediate and certain suppression of the symptoms is naturally the more striking when the symptoms had been severe before. Unless the anatomic conditions favor the pneumothorax it is useless to expect much from it, and consequently its sphere is limited. On account of adhesions preventing the expansion of the pleura the method failed in two cases of hemoptysis.

193. **Serotherapy for Hemoptysis.**—Miliani applied serotherapy in thirty-five cases of various forms of tuberculosis, obtaining the serum from other patients convalescing from tuberculous serositis or using the effusion itself. The doses ranged from 2 to 150 c.c., but, as a rule, he injected between 10 and 50 c.c. every day or at intervals of one or two days. The injections were subcutaneous (220) or injected directly into the peritoneum or pleura (54), and the number ranged from three to thirty-three, averaging about five or ten except in the hemoptysis cases. The effects were constantly good in the cases of tuberculous pleurisy or peritonitis, the symptoms subsiding to a clinical cure. No recurrence is known to date —over six months—in any instance. In the cases with mixed infection little benefit was realized. The tendency to pulmonary hemoptysis was arrested in every case and by a single injection, and the hemorrhage was also permanently arrested in a case of hemorrhagic nephritis. This patient was a man of 28 free from tuberculosis, malaria and syphilis. The blood disappeared from his urine after the second injection of 50 c.c. from a healthy young man; 20 c.c. of the same serum apparently arrested rebellious hematemesis in a case of gastric cancer. In sixty-four of the 278 injections made the fluid was pleural effusion or ascitic fluid. These fluids cause various disturbances, chills, headache and abdominal pain if injected unmodified, but not if defibrinated and exposed to the sun for forty-eight hours. With this nothing was observed suggesting serum sickness.

202 From the Balkan Seat of War. (Fra serbiske Krigslazaretter.) J. Stürup.

199. **Rheumatic Headache.**—Lorenzen says that after excluding other causes for the headache we can sometimes explain it by discovery of tender lumps under the skin of the head and neck. There is evidently some inflammation of the fibrous tissue, causing the headache, and this fibrositis usually yields to skilful massage. The fibrositis generally involves more or less of the adjoining muscles in the neck and its first development may date from childhood. The chronic tendency of all rheumatic affections is evident here, and the intervals between exacerbations are short as a rule so that patients with headache from this cause are seldom long free from it at a time. The attacks are brought on by slight indiscretions in diet or exacerbations of a chronic throat or nose affection, or by long straining to write or watch a performance. The patient may wake with headache and a little stiffness in the muscles involved, and he remarks that he must have slept with his neck in some unnatural position. The constant slight irritation may entail nervous irritability. Chilling of the head may bring on an exacerbation; in women this may occur after washing the hair. When the rheumatic origin is suspected, the entire head, front and back and the neck should be palpated. During the periods of calm, palpation may not cause pain. When the nerves can be palpated on a firm background they may occasionally feel irregular and thickened, but this is rare. The scalp seems thickened in parts, and the skin at the base of the skull may lie in ridges. The pains are vague and hard to locate; the sensation is a vague feeling of oppression, pulling or tenderness of the tissues, and there may even be a tendency to dizziness. There is generally total relief from pain after the massage.

204 *Chronic Suppuration in Infant's Ear. (Om det kroniske suppurative Øreflod i den spæde Barnealder og dets Profylaxe.) F. Pontoppidan.

203. **Utilization of Absorbed Light Rays in Therapeutics.**—A previous communication on this subject by Brinch was summarized in THE JOURNAL, Oct. 26, 1912, p. 1586. He here reports additional cases and reviews his experience with a total of seventy cases of pulmonary tuberculosis and a number of other localizations of tuberculosis. He regards the results as very encouraging. The effect of the treatment was much greater with surgical tuberculosis than with pulmonary lesions. This experience confirms Rollier's with direct sunlight, tuberculous lesions in lymph-nodes and bones being far more amenable to treatment by radiation.

204. **Chronic Suppuration in the Ear in Young Infants.**—Pontoppidan insists that this condition is more common than generally realized, and that it is frequently the unsuspected cause of deafness later and even of deafmutism. The discharge from the ear is liable to prove extremely rebellious to all measures and he explains this as owing to the peculiar anatomic conditions at this age in this region. The antrum is predominantly involved, and he declares that any suppuration in the antrum of an infant which persists for from four to six weeks, even if there are no symptoms except a profuse purulent discharge from the ear, should be treated without delay by cutting into the mastoid antrum. The anatomic conditions render the operation far simpler and easier than in adults, and even the youngest infants bear the little operation without harm. He has performed it in seven cases, as he relates in detail, the children under one or two years of age. In his 309 mastoid operations, 131 were on children under 15, including the seven infants..

206 Innervation of the Sternalis Muscle. A. Strandberg.

ing with the external cutaneous and anterior femoral nerves, and Pinkus[17] and Morris[18] have each reported a zoniform case. On the other hand, in the case shown before the Dermatological Society of the Netherlands, by Mendes Da Costa, in 1901, the groups of lesions were situated along the metameric segments of the skin described by Head, and there was no possible connection with the distribution of the peripheral nerves, cutaneous or subcutaneous veins, lymph vessels, or with the lines of Voigt. The lesions formed a linear band on the left leg, and a few were present on the right wrist. On the left leg the exanthem extended upward in two broad bands on the dorsal surface of the ankle over the anterior aspect of the lower part of the leg. Transversely over the upper third of the thigh, parallel with the groin, there was a curved band of efflorescences which extended almost around the limb.

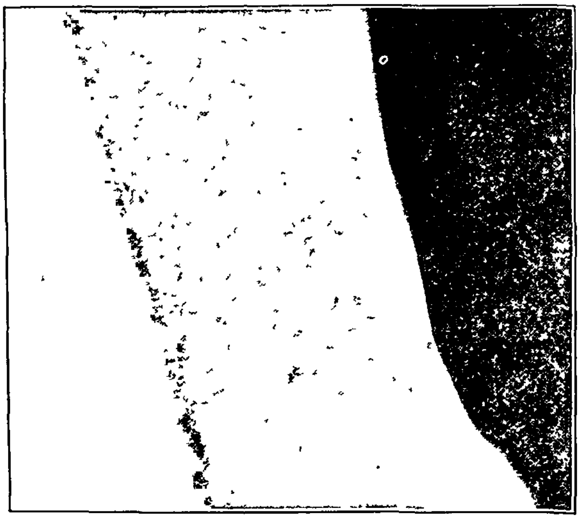

Fig 5, Case 2—Lichen planus bullosa, showing lesions on wrist.

In my opinion the most plausible explanation is found in those cases in which the eruption follows scratch-marks or other local injuries of the skin, as in the cases reported by Hallopeau and Jamier,[19] Morris,[20] Abraham,[21] West[22] and Walters.[23] It is a well-recognized fact that in certain systemic infections which are characterized by cutaneous eruptions, lues for example, the skin lesions are prone to exhibit a preference for areas of lowered resistance, such as abrasions of the integument due to scratches or tattooing, bruises, or irritation arising from retained excretions or the use of tobacco. Although the cause of lichen planus at present is unknown, I must agree with Norman Walker[24] and others that it presents all of the ear-marks of a generalized infectious process. The cases reported by Montgomery and Alderson,[25] Fordyce[26] and Engman and Mook[27] uphold this theory. Fordyce states that there was little or nothing in the microscopic appearance of the sections in his case that would lend support to the theory of the origin of lichen from nervous disturbance, and decides that it would be more reasonable to suppose we have to do with some poison in the general circulation, which, acting on the papillary blood-vessels, determines the phenomena in question. With this conclusion I am heartily in accord.

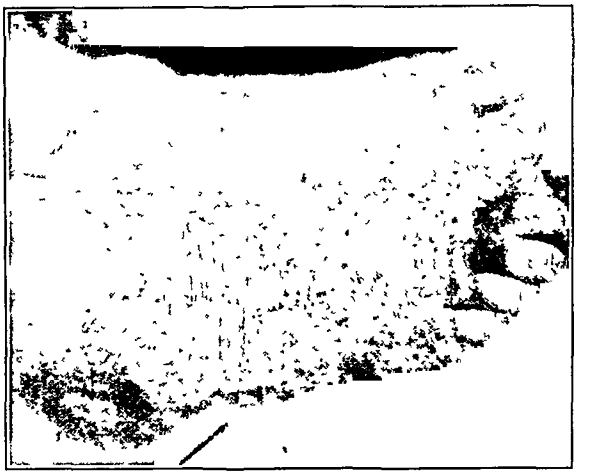

Fig 6, Case 2—Lichen planus bullosa, showing lesions on feet and ankles

While minute collections of serum in the prickle layer and in the papillary region are not unusual in lichen planus lesions, well-defined clinical examples of the vesicular and bullous types of the disease are comparatively rare. Whitfield[28] was able to find only seventeen instances of this complication reported up to 1902, and a fairly exhaustive search of the literature since discloses only five additional, of which the following case is an example:

Case 5.—A housewife, aged 42, suffering from generalized lichen planus, was referred to me, in September, 1911, by Dr. L. L Gullick, of Lamar, Colo. The eruption had been present

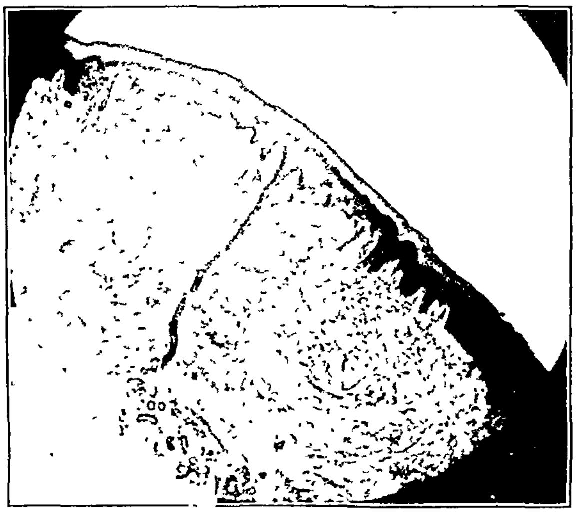

Fig 7—Lichen planus bullosa, showing subepidermal cavity traversed by coil gland duct (low magnification).

several weeks, and the patient had taken a considerable amount of arsenic. When first seen the lesions were of the usual papular type, but at the end of a week several small bullae, averaging 1 cm. in diameter, suddenly appeared on the anterior and inner aspect of the left leg. Two days later similar lesions were found on the right leg. All developed from preexisting papules, and were deep, tense and firm. Permission to perform a biopsy was refused. A blood-count made at this time showed nothing abnormal. Some of the lesions were ruptured by accident. The others disappeared in the course of a few days.

Recently I had an opportunity to study a second and much more severe case.

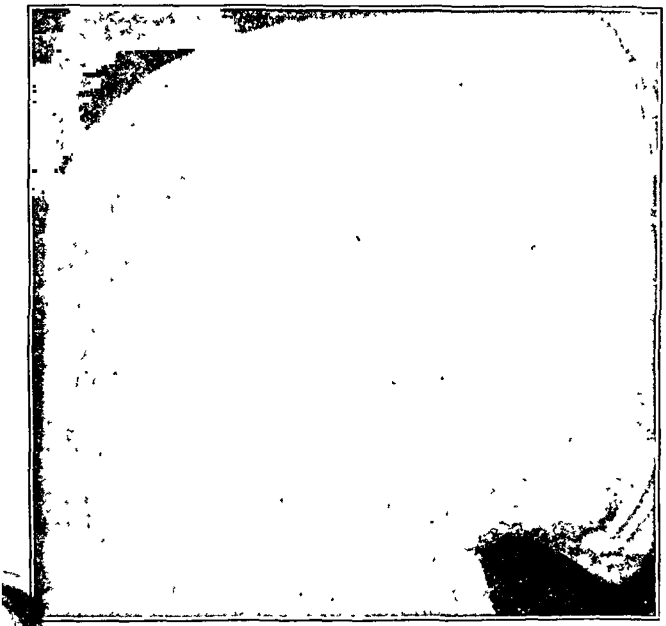

Fig. 8.—Atrophic lichen planus.

CASE 6.—A housewife, aged 63, a native and resident of Macomb, Ill., was referred to me by Dr. A. G. Koch, of this city, in May, 1913. The malady had existed since August, 1912. The usual lichen planus areas (the flexor surfaces of the forearms and the inner surfaces of the thighs) were the regions principally involved, although the neck, trunk, legs and feet also were affected. The itching at times was intense, and the patient was weak and exceedingly nervous. The first outbreak of bullae occurred in September, 1912. At that time only local applications had been employed in the treatment of the disorder. A papular lesion would be converted into a vesicular one by friction alone (a clinical observation first recorded by Allen[29] in 1902). On the other hand, vesicles frequently developed suddenly and without appreciable reason on smooth and apparently normal surfaces. Infection with staphylococci occasionally occurred, and slight scarring was not infrequent. Several times during the winter the eruption disappeared almost entirely but invariably recurred. When I first saw the case the forearms and the lower limbs were densely studded with papules, and on the wrists (Fig. 5), ankles (Fig. 6) and inner surfaces of the thighs were many, a hundred or more, tense, thick-walled bullae. These lesions were oval or circular in outline, from 0.5 to 1 cm. in diameter, and occasionally were grouped in a semicircular manner. None were hemorrhagic. Shortly after the case came under observation one of the angular papules on the left arm was excised and examined microscopically. It presented the usual histologic picture of papular lichen planus lesions. A few days later a small but well-defined vesicle, which had developed suddenly on apparently normal skin and was about eighteen hours old, was removed without anesthesia from the inner border of the right hand.

The specimen (Fig. 7) was fixed in formaldehyd solution and imbedded in celloidin. The corneous layer was condensed and thickened. The granular layer was little changed. The rete was decreased in thickness and the cells were edematous, with occasional "balloon" forms, and stained poorly. A few leukocytes and many small, deeply stained round cells lay in the interstices along the ragged under surface of the epidermis. The main collection of fluid was found between the basal layer of the epidermis and the corium. The cavity was elliptical, its long axis parallel with the surface of the skin. Extending upward through the middle of the bulla was a well-preserved coil-gland duct

Throughout the section, which was exceedingly edematous and boggy, cellular infiltration was a conspicuous feature. It was greatest, as might have been expected, in the immediate vicinity of the cavity, but in the neighborhood of the coil-gland and duct, as well as in the perivascular regions, the peculiar round, sharply stained cells so characteristic of the disease were exceedingly numerous. The elastic fibers in the upper corium had disappeared, and those in the subpapillary region were swollen and degenerated, and stained faintly and unevenly. Judging from the tinctorial reactions it is probable that the changes in the elastic tissue are secondary and not primary manifestations. Sections stained by the Gram-Weigert method showed no micro-organisms.

The cause of bullae formation in these cases is as interesting as it is little understood. Colcott Fox[30] was the first to suggest that the complication might sometimes be due to arsenic. Allen[31] believed that the outpouring of serum producing the vesicle might have some connection with a vitiated coil-gland secretion. Engman[32] holds the opinion that the development of bullae is dependent on three factors: (1) an unusual tendency to edema, (2) a very firm and non-edematous epidermis, and (3) certain degenerative changes in the elastic fibers. The occasional occurrence of suppuration, with or without subsequent ulceration, as described by G. H. Fox,[33] is largely a matter of resistance, on the part of the patient, to staphylococcic infection. When one considers the histopathology of lichen planus, it appears strange that cutaneous atrophy is so frequent a sequel

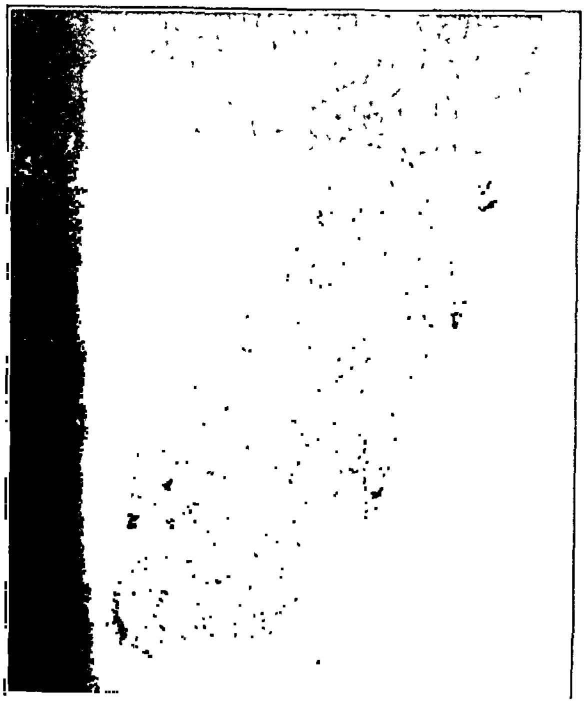

Fig. 9.—Lichen planus hypertrophicus (twenty-five years' duration).

to the affection. Excluding the cases of so-called "white spot" disease, which probably are representatives of Unna's card-like scleroderma,[34] and the lichen planus atrophicus et sclerosus of Hallopeau,[35] which includes von Zumbusch's lichen albus,[36] and which, strictly speaking, does not belong in the group under discussion at all, lichen planus with subsequent atrophy is a comparatively rare condition. The following example is fairly illustrative of this type:

Case 7.—A. G., a pharmacist, married, aged 46, was referred to me by Dr. B. F. Coffin, of Kansas City, Kan., in October, 1911. The eruption was confined to the cervical and the crural regions, and consisted of dark red, angular, burnished, itchy papules which had been present several months. A few of the papules on the left side of the neck had disappeared, leaving punctate, white scars, and in some of the patches on the limbs similar changes had taken place. On the inner surface of the right knee (Fig. 8) was a sharply defined group of pin-head sized atrophic areas which the patient stated had been present about one month. Prior to that time the lesions had been papular, and the seat of paroxysmal attacks of intense itching.

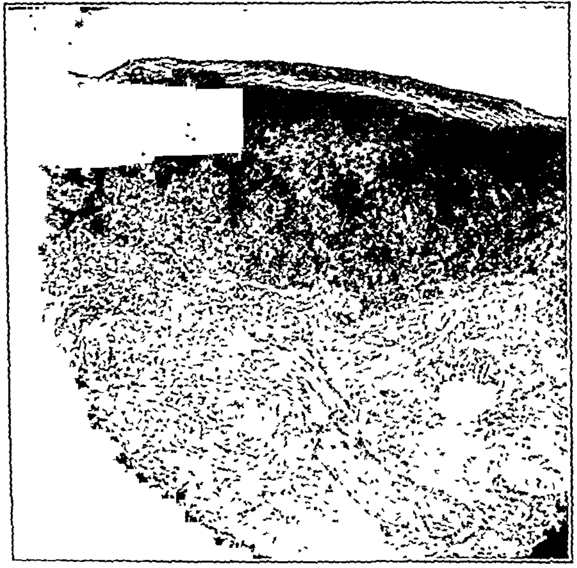

Fig. 10.—Lichen planus hypertrophicus, showing corneous hypertrophy, acanthosis, dilatation of lymphatics and cellular infiltration in the papillary region (moderate magnification).

A piece of tissue was excised from near the center of the patch for microscopic examination. The histologic appearance closely resembled Darier's description of Hallopeau's first case[35] of lichen planus sclerosus et atrophicus. The corneous layer was thickened, as was also the stratum granulosum. The prickle layer was reduced to about one-half its usual depth, and many of the cells were shrunken and misshapen. The papillae had almost entirely disappeared. There was condensation and hypertrophy of the collagen bundles in the upper corium, with wide-spread cellular infiltration in the deeper regions, particularly in the neighborhood of the blood-vessels.

Lichen planus verrucosus is sometimes only a variety of lichen planus hypertrophicus in which the papillae are enlarged and have an irregular wart-like horny covering. Warty patches may also form primarily, from the aggregation of papules developing around the hair follicles of the lower extremity, and rarely on the upper.[37] An instance of the latter type came under my care in March, 1912.

Case 8.—A woman stenographer, aged 38, was referred to me by Dr. Eugene Carbaugh, of this city. Following a generalized attack of lichen planus in January, 1912, the eruption disappeared only partially, numerous papules remaining on the forearms, thighs and legs. On the outer side of the right leg the papules evinced a predilection for the margins of the follicular openings (probably a result of friction from the skirt hem, as the patient was fond of walking), with a resultant formation of a rough, nutmeg-grater-like, brownish patch, 5 cm. wide and 10 cm. long, and consisting of a score or more of irregular, cone shaped, scaly papules, varying from 0.5 to 1 cm. in height, each pierced through the center by a single stiff hair. There was considerable infiltration, but the itching was not nearly so severe as in the other affected regions. A biopsy was not permitted

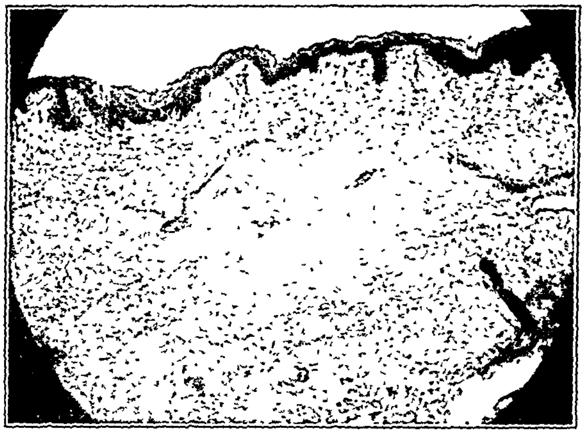

Fig. 11.—Lichen chronicus simplex (Vidal) (moderate magnification).

Fig. 12.—Prurigo nodularis.

Well-defined examples of lichen planus hypertrophicus, a type which has been carefully studied histologically by Fordyce[38] and Lieberthal[39] in this country, Max Joseph[40] in Germany, Crocker[41] in England and Brocq[42] in France, are comparatively common in the middle

West. Within the past three years I have seen more than a dozen cases. The following instance, which is quite typical, will serve as an example:

Case 9.—A. L., a pharmacist, married, aged 67, was referred to me by Dr. C. D. Lloyd, of Leavenworth, Kansas, in October, 1912. There was an indistinct history of an intensely itchy, generalized eruption which had occurred about thirty years previously and lasted several months. For over twenty-five years the patient had suffered at intervals from a rough, dry, scaly lesion on the outer side of the right leg. The skin on other parts of the body was normal. The affected area (Fig. 9) was kidney-shaped, about 8 cm. in width by 20 cm. in length, and had changed little if at all during the past two decades. The surface of the lesion was rough, almost verrucose. The edges were oval, and "sandpapery" to the touch. The underlying tissues were infiltrated. The itching at times was so intense that considerable portions of epidermis were frequently removed by the patient's finger-nails in an effort to secure relief. A piece of skin was excised from the lower end of the lesion, no anesthetic being employed (strange to say, the old, chronic, thickened patches are comparatively insensitive to pain), and stained by the usual methods. It exhibited the characteristic histologic features (Fig. 10) of lichen planus hypertrophicus.

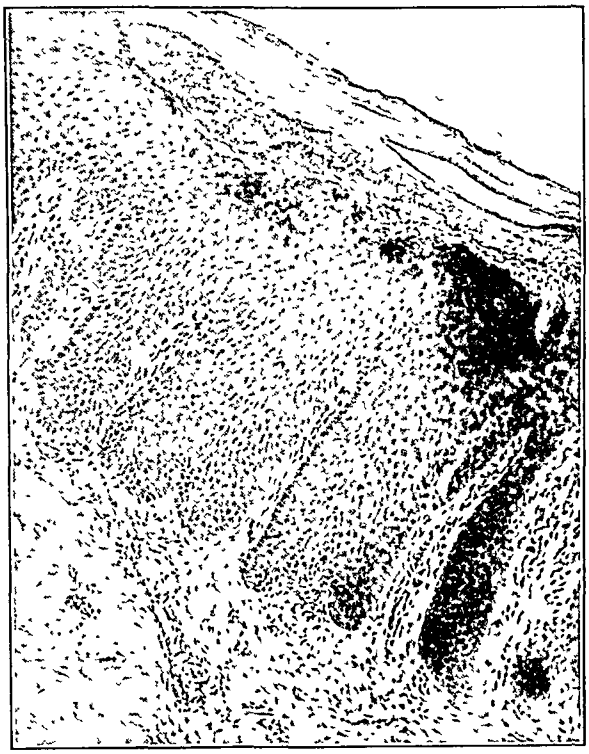

Fig. 13.—Prurigo nodularis from an early lesion, showing moderate hyperkeratosis, acanthosis, vesiculation, increase in width of interpapillary processes, and character and distribution of cellular infiltrate (moderate magnification).

The exact position occupied by lichen chronicus simplex (Vidal[43]) has long been a disputed question. Vidal would place it with the lichens, Brocq and Jacquet[44] consider it a representative of the neurodermatoses, Stelwagon[45] classes it with the eczemas, and Crocker[46] agrees with Besnier[47] that the condition is not a pathologic entity, but may represent eczema, seborrheic dermatitis or lichen planus. Judging from a clinical and histologic study of three cases of the affection, I agree with Brocq and Jacquet that the disorder is a circumscribed pruritus with subsequent lichenification. Itching without eruption is the first symptom, and the lichenification is probably a reaction which the skins of some individuals exhibit to long-continued trauma (from scratching) with ensuing subacute inflammatory involvement of the affected area.[48]

In the cases studied, the lesion was located in the left cervical region in two instances and on the inner surface of the thigh in the third. The eruption was very similar in the three, sharply defined, round or oval, dollar-sized or larger patches of subacute dermatitis, the surface being dry, slightly scaly, and marked into numberless little squares and diamonds by tiny, criss-cross wrinkles (exaggerated surface markings). Wickham's gray points and striae[49] were absent. The histologic findings in the three cases were practically identical, varying only in degree. The corneous layer was somewhat thickened (Fig. 11). The stratum granulosum had disappeared. The rete was reduced in depth, and the constituent elements stained poorly. The prickle layer was of uniform depth throughout, and the stratum corneum tightly adherent. In consequence, each interpapillary depression was marked by a corresponding groove in the epidermal covering. The papillary and subpapillary layers of the corium were sclerosed, and there was considerable collagenous degeneration, with resulting reaction to the basic dyes of the connective tissue in these regions. There was cellular infiltration in the corium, particularly in the perivascular regions, but this was not a conspicuous feature. The intruding cells were oval or elongated and as a rule lay parallel to the vessels. The elastic fibers were attenuated and lessened in number.

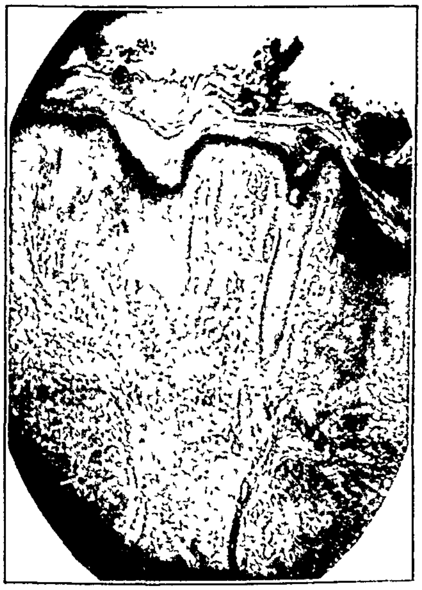

Fig. 14.—Prurigo nodularis, from an old lesion on the leg (moderate magnification).

In 1900 Brocq[50] described an exceedingly chronic, itchy, lichenoid, papular dermatosis of which he had seen five examples. Following Unna's suggestion on group classification,[51] he named the disorder "lichen obtusus corneus." The lesions were few in number and asymmetrically distributed over the body, affecting principally the extremities. They began as papules, and in the course of weeks or months developed into hard, dry, grayish or yellowish, dome-shaped nodules, about 1 cm. in height and 2 cm. or more in diameter. Histologically, the lesions bore slight resemblance to those of lichen planus, and Brocq believed that the affection might be separated from the lichen planus group and ranged with the neurodermatoses—pruritus with subsequent lichenification.

More recently Hyde,[52] basing his conclusions on the study of a similar case occurring in his own practice and also on the reports of Hardaway,[53] Morrant Baker,[54] Johnston,[55] Hjelman,[56] Schamberg and Hirschler,[57] C. J. White[58] and Jackson,[59] all of whom have reported cases more or less similar to those described by Brocq, has suggested the name of prurigo nodularis for the affection, and it is probable that this designation will be generally adopted.[60]

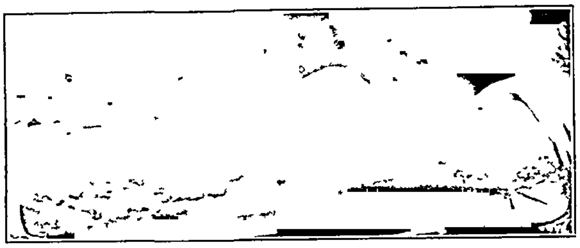

Fig. 15.—Lichen ruber moniliformis, showing arrangement of lesions on the lower limbs.

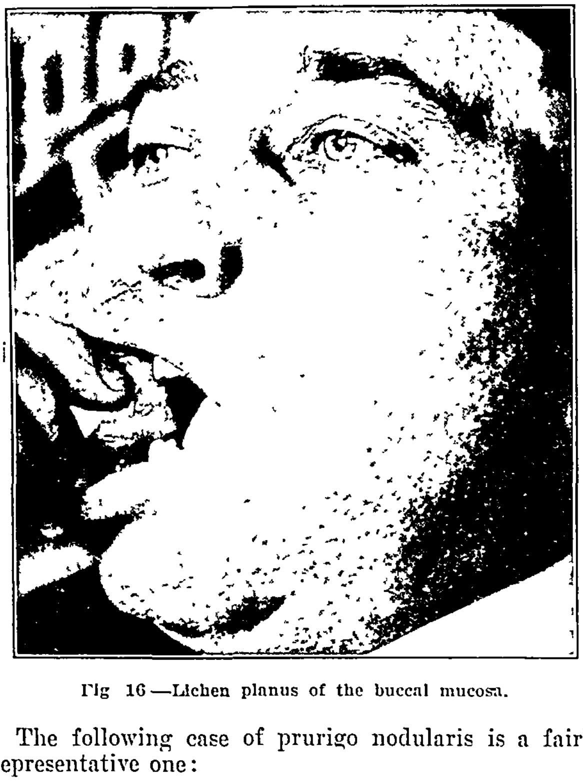

Fig 16.—Lichen planus of the buccal mucosa.

The following case of prurigo nodularis is a fairly representative one:

CASE 10.—L. H., a single woman, aged 31, was referred to me by Dr. John A. Dillon, of Larned, Kan., in November, 1912. The patient was a native of Missouri and a resident of Kansas. The personal and family histories were negative. The disease first appeared as a slight hyperemic area on the inner side of the right thigh, three years before. This was followed by the development of a papule, and later a scaly nodule. In the course of a few months similar lesions appeared on various parts of both upper and lower extremities. The eruption consisted of forty or more large, flat papules (Fig. 12) or nodules, 1 to 2 cm. in diameter, circular or oval in outline, grayish, and covered with tightly adherent scales. The itching at times was so severe as to be almost unbearable. For laboratory study five of the nodules in various stages of development were excised, cocain being employed for anesthesia. In passing, it may be stated that all of the growths recurred, reaching their original size in the course of a few weeks.

The sections of the earlier lesions resembled those from both Johnston's and Zeisler's cases (Dr. Zeisler was kind enough to loan some of his specimens for comparison), but were less keratotic than those described by C. J. White.[58] Many of the interpapillary downgrowths were quite broad (Fig. 13), the granular and spinous strata were well preserved, and in a few instances a tendency to vesiculation was noted. The prickle layer was increased in depth, and an occasional leukocyte was found lying in the intercellular spaces. The lymphatics were dilated, both papillary and subpapillary layers were edematous (Fig. 14), and there was considerable cellular infiltration throughout the corium, particularly in the vicinity of the capillaries and the nerve-trunks (a peculiarity which Welch has pointed out as occurring in Johnston's case). The coil-glands and ducts were unaffected. Keratosis and interpapillary downgrowth increased with the age and severity of the lesions, and in one of the older nodules several epithelial pearls and two giant-cells, of the foreign body type, were found, changes which have never before been described as occurring in this disorder. In sections stained[61] by Bielschowsky's method sensory nerve-endings in very considerable numbers were found in a few of the papillae.

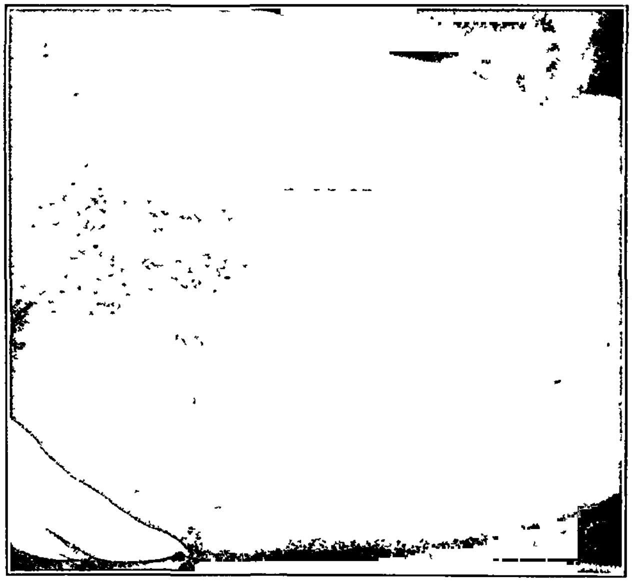

Fig. 17.—Lichen ruber moniliformis, showing scars on back and shoulders.

In 1886 Kaposi[62] reported an extraordinary example of what he believed to be lichen planus. The eruption consisted of papules, nodules and plaques, and the back, abdomen, neck and limbs were affected. The trunk, particularly in the clavicular regions, showed numerous cicatrices, the sites of former papular lesions. The most striking feature, however, was the arrangement of the eruption on the extremities. Here the nodular masses, many of which were 1 cm. or more in diameter, were disposed in rows like the beads of a necklace. Histologically, "both the primary and secondary spots were found to consist of a dense cellular and nuclear infiltration of the subpapillary layers of the corium, without any trace or structure of connective tissue. There were found only cells, many naked and polymorphous nuclei, biscuit and half-moon shaped, and many cells with the appearance of retrograde metamorphosis, distended, and undergoing cloudy swelling, a good many giant-cells, and the feathery-like outgrowth of the external root-sheath, better seen in lichen ruber than in any other chronic dermatosis, may here be well seen."[63] Kaposi named the condition "lichen ruber moniliformis." Although the Vienna dermatologist apparently did not doubt the nature of the disorder, others did. Unna, especially, criticized the diagnosis from a histologic point of view. The following case, which resembles the one described by Kaposi very closely, has been under my care during the past ten months.

Case 11.—W. W., a gardener, married, aged 46, was referred to me by Mr. A. N. Doerschuk, of this city. The patient was a native and a resident of Missouri. His history was negative as to cutaneous disorders and so was that of his family. Venereal infection was denied. Wassermann tests, made on two different occasions, were negative. There was a slight reaction to tuberculin by the von Pirquet method, none by injection. Both blood and urine were normal. The cutaneous disorder from which he was suffering had been present seven years, and had commenced as a generalized pruritus. This persisted for several months and was followed by an eruption of round-topped, scaly, flesh-colored papules which always remained dry but were never burnished or shiny. Itching was paroxysmal and intense. During the next two years many of the papular lesions increased in size, but a few on the chest disappeared without treatment, leaving white, hypertrophic scars. Many of the large papules on the extremities exhibited a tendency to form bead-like bands, from 3 to 15 cm. in length, parallel with the long axis of the limb. As a result of the continuous worry, discomfort and loss of sleep the patient became almost a physical wreck. On examination numerous moniliform lesions were found on the thighs (Fig. 15), and arms, and a few large, solitary nodules were scattered over the trunk and the extremities. The mucous membranes were not affected. Over the back (Fig. 17) and in the clavicular regions were a number of thick, white cicatrices. Many of the active lesions were lacerated and bloody from scratching. The face, hands and feet were free. There was present no scaliness of the scalp nor thickening of the palmar or plantar integument. The dorsal surface of the fingers and hands was normal in every way.

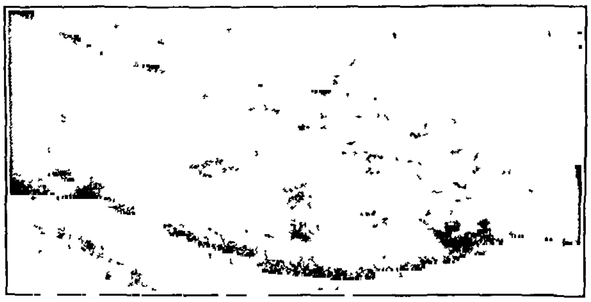

Fig. 18.—Lichen ruber moniliformis. Inner surface of left leg.

At various times nine pieces of tissue were removed for microscopic study; one from a scar, two from nodules and the rest from moniliform lesions. Sections from the cicatricial specimen exhibited, with the exception of a slight hyperkeratosis, the characteristic histologic features of scar tissue. The lesions on the back and shoulders probably were largely traumatic, caused by scratching the papules. The nodules and the moniliform lesions were similar in structure (Fig. 18). The corneous layer was greatly thickened. The stratum granulosum and the basal layer were well preserved. The interpapillary processes were longer and wider than usual, and at many points in the rete the cells were swollen and edematous.

Throughout the corium the lymphatics were dilated (Fig. 19), and both the papillary and subpapillary regions were infiltrated with round cells, leukocytes and mast-cells. The sebaceous and coil-glands were affected but little. The elastic tissue in the upper corium was sparse and degenerated. In the Gram-Weigert sections no micro-organisms could be found.

Since 1886 cases of lichen ruber moniliformis have been reported by G. H. Fox,[64] Bukovsky,[65] Rona,[66] Gunsett[67] and Hyde.[68]

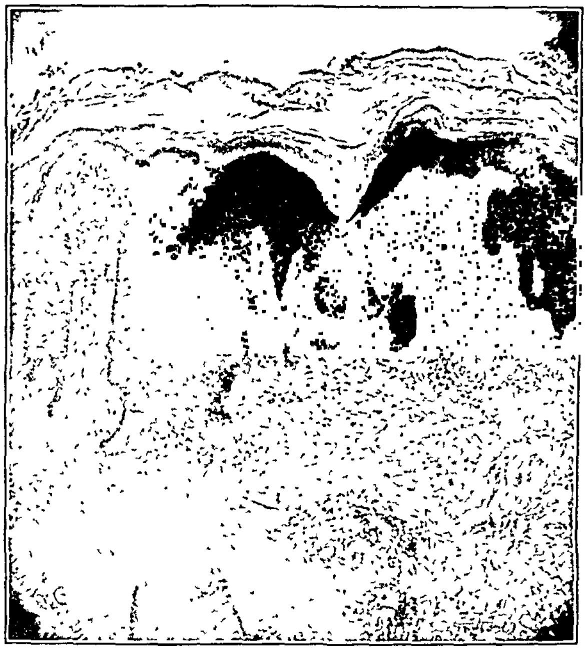

Fig. 19.—Lichen ruber moniliformis, showing hyperkeratosis, persistent granular layer, acanthosis, lymphatic dilatation, and widespread cellular infiltration throughout corium (moderate magnification).

Dr. Fox[69] considers his case an example of pityriasis rubra pilaris.[70] Although the cases presented by Bukovsky, Gunsett and Hyde (I have not access to Rona's report) were undoubtedly examples of lichen planus in which many of the lesions were arranged in a moniliform manner, to me none of them bear much if any resemblance to the case portrayed in Kaposi's colored plate, and a comparative study of the histopathology is even more disconcerting. Consequently, I must agree with Unna that Kaposi's case of "lichen ruber moniliformis" was not a case of lichen planus at all. On the other hand, a comparison of the case reported by him with those that are now regarded as examples of prurigo nodularis is very suggestive, and I consider it not unlikely that his patient and the one of mine, whose history is here recorded, were afflicted with the latter malady. Although there are some minor differences in the histologic details, the changes present are far more characteristic of prurigo nodularis than of lichen planus.

TREATMENT

As Stelwagon[71] so sanely says, "the patient is to have the benefit of good plain food, hygienic living, and, when possible, outdoor life and freedom from mental worry or care." As a remedial agent, I have found mercury, as originally recommended by Liveing, immeasurably superior to arsenic. It is best given intramuscularly in the gluteal region, and in combating this disorder I prefer the soluble to the insoluble preparations, because of the greater ease with which the effects can be controlled. Either the bichlorid, in aqueous solution, or the biniodid, in water or in oil, may be employed. The amount administered varies with the patient, but as a rule the equivalent of 1/12 to 1/6 grain of the bichlorid may be injected once daily. If it is inconvenient to give the drug in this manner, the bichlorid may be given by the mouth, commencing with 1/20 grain, in a half glass of water, and gradually increasing the amount until the physiologic effect is obtained.

In cases of the hypertrophic type the mercurial medication may be alternated, about once a fortnight, with arsenic, or, better, arsenic and iron. Alkaline diuretics, with or without small amounts of bromid to lessen cutaneous irritability, are often beneficial. The salicylates I have found worse than useless, the gastric irritation to which they give rise more than counterbalancing their possible therapeutic value. Salvarsan and neosalvarsan also I have tried without benefit. The local treatment is of importance. A cooling, antipruritic ointment, which is at the same time more or less curative, may be made as follows:

℞	Phenol	♏ v-x
	Menthol	gr. v-x
	Ammoniated mercurial ointment	ʒ ii
	Zinc oxid ointment	ʒ ii
	Anhydrous wool-fat	ʒ iv
	Lime water, sufficient to saturate.	

Make into an ointment. Apply freely two or three times daily.

In addition to an ointment, it is advisable to prescribe a soothing, non-greasy application which the patient may apply at will. One of the best is ordinary calamine lotion, to which has been added from 1 to 10 per cent. of Duhring's coal tar preparation:[72]

℞	Phenol	♏ xv
	Compound tincture of coal-tar (Duhring)	ʒss-v
	Zinc oxid	
	Starch	
	Powdered calamine ... āā	ʒ v
	Glycerin	ʒ iiss
	Water, sufficient to make	℥ vi

Mix. Shake and apply freely several times daily.

If the itching is exceedingly troublesome one may resort to the following combination, for the formula of which I am indebted to my associate, Dr. Kanoky:

℞	Menthol	ʒ iss
	Thymol	ʒ ii
	Chloral hydrate	ʒ i
	Chloroform	℥ ii
	Oil of eucalyptus	℥ ii
	Oil of gaultheria	ʒ iv
	Alcohol, sufficient to make	℥ viii

Mix, shake and apply two or three times daily.

This mixture is as hot as it is efficient, but I have found it of value in many intensely pruritic conditions.

For the eradication of the thick, scaly patches in *lichen planus hypertrophicus*, *numerous methods* have been suggested, none of which are entirely satisfactory. Repeated freezing with Pusey's carbon dioxid snow often is beneficial, and Roentgen therapy in an erythema dose (one sufficient to give rise to an erythematous reaction) or less, constitutes a reliable aid. The long-continued application, under rubber or oiled silk, of *ointments* containing considerable percentages of salicylic acid and tar occasionally results in a cure.

No efficient plan of treatment for prurigo nodularis has yet been devised. For the relief of the itching I have found Bronson's oil[73] (phenol and solution potassium hydroxid, of each, 1½ dram, linseed oil 1 ounce) serviceable, although destruction of the lesions by repeated deep freezing with carbon dioxid snow is probably the best plan.

Commerce Building.

INTRASPINOUS INJECTION OF SALVARSANIZED SERUM IN THE TREATMENT OF SYPHILIS OF THE NERVOUS SYSTEM, INCLUDING TABES AND PARESIS *

WILLIAM H. HOUGH, M.D.
WASHINGTON, D. C.

There is scarcely a disease in which the early institution of treatment is of greater importance than in syphilis of the central nervous system. Many cases are too far advanced to respond favorably to medication by the time they reach the stage of commitment to some institution. As it is not within the scope of this paper to discuss diagnosis, I wish only to emphasize the importance of applying every means at our command in all doubtful cases in order that treatment, if necessary, may be applied before degenerative nerve-tissue lesions set in. *But a few years ago the diagnosis in only about 5 per cent.* of our tertiary nervous syphilitics was properly made, as was shown by the findings on post-mortem examination, where now, with the aid of improved clinical and laboratory facilities, especially the latter, it is only in rare instances that we fail to diagnosticate the disease properly. Indeed, in certain forms of syphilis of the nervous system the condition may be accurately diagnosed by means of modern laboratory tests, months before any *clinical manifestations* appear. *In some of the institutions for the insane in Europe from 25 to 30 per cent. of the patients have been found to be suffering from syphilis. In a few of our state institutions the* annual reports even as late as 1912 do not classify any syphilitics except paretics. This can hardly be, because *they do not have such cases, but probably* is because they fail to recognize them just as was the case at the Government Hospital for the Insane a few years ago before clinical laboratory tests were applied.

Let it not be understood that I consider the diagnosis to be always easily made or that a positive diagnosis can be made *in every case even if all modern facilities* are applied. To illustrate the difficulties in this line, I wish to quote from one of our best authorities, Dr. Smith Ely Jelliffe of New York. He says:

---

* From the Government Hospital for the Insane.

* Read before the Medical Society of the District of Columbia, Oct. 29, 1913.

> There is probably no field in medicine wherein similar disease pictures may arise from so many dissimilar causes as in the domain of the nervous system, nor on the other hand where a single etiological factor may give rise to so many dissimilar pictures. Hence, the necessity for detailed and minute inquiry into all of the possible symptomatology of hereditary and acquired syphilis which in all questionable cases should be supplemented by complete serological and cytological examinations.

That is, we have no symptom or group of symptoms pathognomonic of syphilis of the nervous system, although the inference from some articles is that a certain group of symptoms is practically pathognomonic. There is no doubt that syphilis of the nervous system has increased in frequency in the early stages of the disease, at least since the advent of salvarsan, and this has probably been due, in part at least, to our lack of knowledge as to what constituted an efficient treatment.

Authorities now quite well agree that the most efficient treatment for syphilis of the nervous system as in syphilis in general, in all of its many stages and manifestations is an active combined mercury-salvarsan therapy. The results obtained by ordinary methods of administrations of these remedies in the nervous manifestations occurring in the early stages of the disease have been very gratifying, whereas, in the later manifestations, treatment by ordinary methods has not been encouraging, although a number of instances of good results have been reported. By ordinary methods of administration I mean salvarsan intravenously and mercury by injection or inunction. By later manifestations of the disease, I refer especially to tabes and paresis, two diseases generally classified under the vague term "parasyphilis." I am not prepared to say that the term "parasyphilis" has no further use. It may be an appropriate term to apply, as Watson of England asserts, to primary lateral sclerosis, progressive muscular atrophy, primary optic atrophy and still other conditions mentioned by Fournier, but it is now quite clear that it does not apply to tabes and paresis. It is not my purpose to discuss here the new and important developments that have been evolved concerning the syphilis-parasyphilis question, but it seems essential in view of what follows that they should be referred to briefly. It has now been proved conclusively by Noguchi, Nichols and Graves in this country and by Marie, Levaditi, Foerster and several others in Europe, that paresis is an active syphilitic disease; that is, that living *Treponemata pallida* are present in the paretic brain, and, as Graves has shown, also in the blood, and although we have not as yet exactly the same final proof in tabes, it is quite apparent, for many reasons which may be given, that it is a similar disease affecting a different part of the central nervous system. It should be mentioned that Noguchi has found the parasite in one case of tabes.

That the organisms have not been found as a rule near the blood-vessels, but generally in the gray matter at some distance from them, and that salvarsan appears to have a greater predilection for most of the other tissues of the body than it has for nerve-tissue, as Uhlmann has shown in his studies of the neurotropic action of this chemical, may explain in part the inefficiency of salvarsan administered intravenously in the treatment of these conditions. It has been shown that salvarsan and certain other chemical substances administered intravenously, scarcely, if at all, reach the ventricular fluid, whereas such substances injected into the inferior spinal canal, that is, into the subarachnoid space, readily reach the ventricles, and therefore are thrown into the space which communicates directly with the perivascular and perineural spaces. As it is known that the blood-serum of recently treated or cured syphilitics has a marked trophic action on *Treponemata pallida*, as shown by laboratory experiments, and, as direct injection of salvarsan into the subarachnoid space even in very weak solutions was found, by animal experiments and otherwise, to be injurious, the following technic was devised by Swift and Ellis of the Rockefeller Institute for Medical Research in 1912, for bringing an effective medical agent into more direct contact with the disease-process than appeared to be possible by intravenous administration; the same principle being used which has proved to be so efficient in the treatment of some of the purulent meningitides. We should bear in mind that in the syphilitic diseases of the nervous system we are dealing with a general constitutional disease and not a disease confined to the central nervous system. In paresis, for example, histologic examination has shown that changes are present in many tissues of the body aside from nervous tissue. As will be seen presently, the intraspinous method is only an addition to the modern method of treating constitutional syphilis.

TECHNIC

A dose (generally the maximum) of salvarsan or neosalvarsan is given intravenously in the usual manner. At the end of an hour 50 to 60 c.c. of the patient's blood are drawn by means of venous puncture, clear serum is separated, diluted to 40 per cent. with normal salt solution, heated to 56 C. (132.8 F.) for half an hour, kept cool until the following day, then warmed to body temperature and injected into the subarachnoid space by means of lumbar puncture after the withdrawal of about 15 c.c. of spinal fluid, the amount of diluted serum injected being 30 c.c. (after the first few injections, if well tolerated, I usually inject 40 c.c. of a 50 per cent. serum). It must be injected slowly without much pressure. After the injection the patient is kept in bed for about twenty-four hours with the head lowered.

The number of treatments to be given depends largely on the condition of the patient, but the general rule is to give, if possible, eight or ten treatments, one every second week, then discontinue the treatments for a time, repeating them if necessary, and using as an index the four tests which are now generally known as the Wassermann reaction with the blood, the Wassermann reaction with the spinal fluid, and the cell and the protein estimations of the spinal fluid. As mentioned in the beginning, mercury and iodid, if indicated, should also be administered.

RESULTS

Those who have so far reported results from this method of treatment are the following: Swift and Ellis, Fordyce of New York, Myerson[1] of the Psychopathic Hospital, Boston; Cotton of the Trenton State Hospital; Asper of Baltimore, and myself. About sixty cases in all have been treated, and five hundred treatments have been given. Many of the cases reported have not as yet received a sufficient number of treatments, and but few have been sufficiently observed to allow a statement as to the final outcome. Many of the cases have not been the most favorable for treatment, owing to nerve-tissue degeneration. There has been marked improvement, however, in the syphilitic inflammatory process, as indicated by the four reactions, and in many patients (with tabes especially) there has been pronounced clinical improvement. The following is a very brief summary of the cases of tabes reported by the originators of this method.

---

[1] Myerson, A.: Progress with the Treatment of Paresis by Salvarsanized Serum, Boston Med. and Surg. Jour., Sept. 18, 1913, p. 426. The other reports referred to were made before the New York Neurological Society, Oct. 7, 1913.

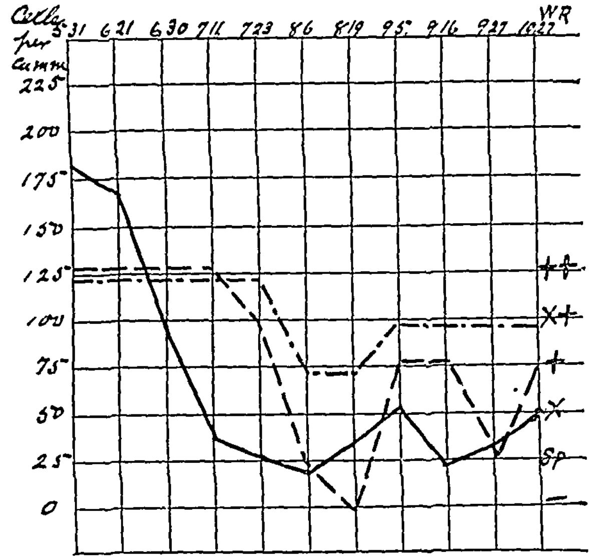

Chart 1, Case 1.—Paresis. In this and the following charts, the solid line is the curve of the cell count, the cells per cubic millimeter being indicated at left; the line of dashes, the Wassermann with blood serum; the line of dots and dashes the Wassermann with spinal fluid; the Wassermann readings being indicated at right (column headed W R): ++, complete inhibition of hemolysis; X+, very slight hemolysis; +, about 50 per cent hemolysis; X, about 25 per cent inhibition of hemolysis; sp, very slight inhibition of hemolysis; —, complete hemolysis. Dates at top show time of treatment and examinations.

Case 1.—Spinal fluid normal for over one year. Free from pain. No advance in tabetic process.

Case 2.—Spinal fluid normal for nearly one year after discontinuance of treatment. Returned to work. No advance in tabetic process.

Case 3.—Ten intraspinous treatments alone—no intravenous treatments. Most striking symptomatic improvement as well as return of spinal fluid to normal.

Case 4.—Patient received only four intraspinous treatments and would not continue. Spinal fluid returned to normal. Less marked symptomatic improvement.

Case 5.—Spinal fluid normal except for slight globulin increase.

Case 6.—Spinal fluid normal but Wassermann positive in blood.

Case 7.—Spinal fluid normal. Wassermann diminished in blood.

Case 8.—(Especially significant.) Patient took treatment followed by improvement in spinal fluid. Refused treatment for eight months and had a relapse with increase in the spinal fluid findings. Took treatment again followed by symptomatic improvement and return of fluid to normal.

Case 9.—The advantage of combined intraspinous and intravenous treatment were shown in this case. Reactions disappeared under the combined treatment and reappeared under intravenous treatment alone.[2]

So far as tabes is concerned the reports by others show about the same general results. In paresis, improvement has been reported in many instances; every worker having obtained some favorable results. The best results in paresis were reported by Cotton, Myerson and Aper. In three of nine cases treated by Cotton, the patients were sufficiently improved to be discharged from the institution, and some improvement was shown in five others. One juvenile patient, after having numerous convulsions, returned to an apparently normal condition with the exception of the pupillary reactions. In this disease it must be remembered that we are dealing with a more difficult problem than in tabes, inasmuch as the disease-process is more inaccessible and affects a more vital part of the nervous system. Here it is especially important that treatment should be instituted early in the disease. In the later cases, however, the indications are that the inflammatory syphilitic processes may be arrested. If we are able to arrest the process in paresis and tabes — and the evidence so far, in some cases, is strongly in favor of this possibility — a marked advance will have been made in the treatment of these hitherto almost invariably incurable diseases.

The most favorable results may be obtained, as naturally would be expected, in the nervous manifestations which occur in the earlier stage of syphilis.

My own experience consists of thirty-six treatments administered to six patients. As two of the patients received but one treatment each, I shall report but four cases.

Case 1.—Patient, aged 37. Periodic drunkard. History of syphilis. Antisyphilitic treatment just before admission. Pupils contracted and with slight reaction to light. Slight Romberg. Patellar reflexes abolished. Delusions of grandeur. No insight into his condition. Noisy and disturbed a great deal of the time. The four reactions positive. Ten treatments.

The patient now has gained 27 pounds, is quiet and orderly, has gained insight into his condition, is but slightly euphoric, and his delusions are not prominent. Pupillary and patellar reflexes are unchanged.

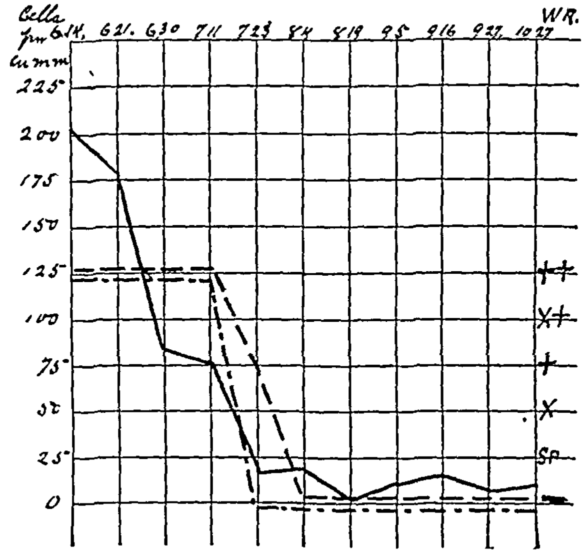

Chart 2, Case 2.—Paresis.

Case 2.—Patient, aged 38. No history of syphilis. Pupils react sluggishly to light. Patellar reflexes exaggerated. No incoordination. Numerous delusions of grandeur. At times destructive, noisy and excitable, frequently has to be restrained. The four reactions positive. Ten treatments.

The general physical condition of the patient has improved. He is now quiet and orderly and the delusional state, though still apparent, is not quite so prominent as on admission.

Case 3.—Patient, aged 32. No history of syphilis obtainable. History of gonorrhea and excessive use of alcohol. Onset of mental symptoms sudden about one week before admission. Pupillary anomalies, incoordination, marked tremors of the facial muscles, tongue and extended fingers. Deep reflexes markedly exaggerated. Manifold delusions chiefly of a disagreeable and depressing character. Patient excited, noisy and disturbed the greater part of the time. The four reactions positive. Nine treatments.

---

[2] For detailed report of these cases see Swift H F and Ellis A W M: The Treatment of Syphilitic Affections of the Central Nervous System with Especial Reference to the Use of Intraspinous Injections, Arch Int Med, Sept 15, 1913, p 331.

There is practically no change in the patient's condition except that his general physical condition has improved. He has gained in weight.

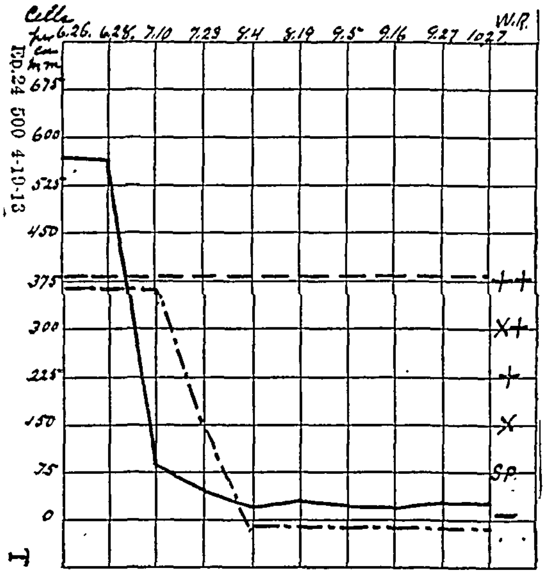

Chart 3, Case 3.—Paresis.

Case 4.—Patient, aged 20. Family history unimportant. The patient, at 16, enlisted in the U. S. Navy. After having been confined in a naval prison for several months the patient was returned to duty on the U. S. S. *Maine*, where he remained for about two weeks when a chancre on the frenum developed and he was sent to the Philadelphia Naval Hospital for treatment, July 18, 1912. The following notes were taken from the naval health record: July 22, 1912: Wassermann reaction strongly positive; 0.6 gm. salvarsan given intravenously. July 25: 0.6 gm. salvarsan given intravenously. August 20: Patient complained of pain in his right ear. This continued until August 26, when a facial paralysis of the right side developed. August 31: Condition unchanged. September 10: Potassium iodid and mercuric chlorid given by mouth. September 25: Facial paralysis much improved. September 30: Complaint of severe headache for two or three days. October 1: Partial paralysis of the left arm and leg and right side of the face, which became complete the next day. Patient vomited frequently, was in a semistupor, could not articulate, swallowed with difficulty, had some lateral nystagmus the left eye deviating to the left and a temperature of 101.3 F. October 6: Temperature normal. Given mercurial inunctions and bichlorid, one-fifth grain intramuscularly. Understands what is said to him but cannot reply. October 8: Temperature 101 during night; 1,500 c.c. urine passed in twenty-four hours containing trace of albumin. October 11: Improving slowly; writes his wants; moves his left leg slightly. October 19: Given 6.4 gm. of salvarsan intramuscularly; mercury and iodid continued. November 1: Patient moves left leg at will but strength is impaired; can move left arm slightly. November 5: Patient improved in strength and motion of paralyzed side; walks with the aid of crutches. December 15: Patient able to walk short distances without the crutches, but drags the left foot. December 31: Generally improved. January 5: Complaint of headache; temperature 100; given mercury by inunction. January 20: Occasional attacks of vomiting; complaint of failing eyesight. January 30: Complains a great deal of headache. February 28: Complains of headache; given mercury and iodid by mouth in place of inunctions. March 20: General condition unchanged. April 1: Passes urine and feces involuntarily; is sullen and seems to try to cause trouble. April 25: Mental condition somewhat improved; tries to walk occasionally. May 10: Has hysterical outbursts and is impaired mentally; when questioned he laughs in a silly manner and does not seem to comprehend what is said to him. June 9: Surveyed by a board of medical survey and recommended for transfer to the government hospital for the insane as having cerebral syphilis. July 12: Patient transferred to the government hospital for the insane.

On admission patient was rather poorly nourished. There was a spastic paralysis of the left arm, paralysis of the left leg with considerable tremor and partial paralysis of the right side of the face. The deep reflexes on the right side of the body were about normal, on the left side exaggerated. There was ankle-clonus and typical Babinski on the left side. The tongue showed a fine tremor. Patient was unable to stand and showed considerable muscular incoordination. He passed urine involuntarily. The pupils responded sluggishly to light and accommodation and the movements of the right eye were somewhat impaired. The patient was oriented as to time, person and place; some lack of insight into his condition; no hallucinations; no delusions; considerable slurring and stammering over test words and considerable emotional instability. Memory was fairly good. Wassermann reaction with the blood-serum was completely positive. There was cerebrospinal pleocytosis with increase of protein. Wassermann reaction with the spinal fluid was negative.

This patient with typical nervous relapse following the use of salvarsan has received since admission into this hospital, six intravenous injections of neosalvarsan each of 0.9 gm. and five intraspinous injections, also mercury and iodid. There has been pronounced clinical improvement as well as improvement in the blood and spinal-fluid findings.

It is too early to predict what the outcome will be in the cases here reported, but we see pronounced improvement in the four reactions in all, and symptomatic improvement in three. We should bear in mind that improvement and remissions in paresis are not uncommon, but when we see at the same time improvement in the four reactions it appears to me to be of considerable significance. I may add, in connection with the clinicopathologic tests, that in the study of the cerebrospinal fluid in 240 cases of paresis, some of which have received various kinds of treatment and in many of which repeated punctures were made, I have never seen

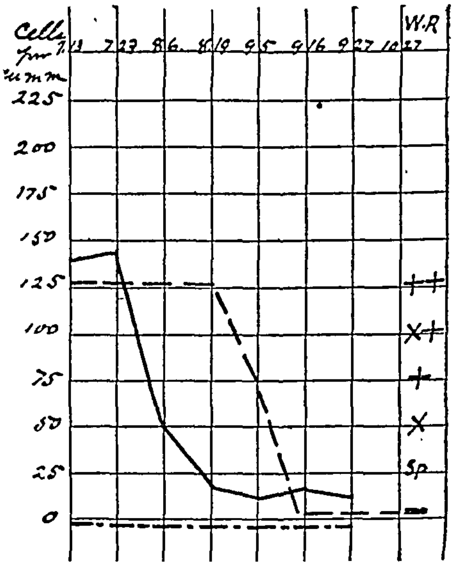

Chart 4, Case 4.—Cerebral syphilis.

such pronounced improvement in the reactions as occurred under the intraspinous injections.[3]

On the charts I have endeavored to show three of the four reactions, namely, the cell content of the spinal fluid, the Wassermann reaction in the spinal fluid and the Wassermann reaction in the blood. The charts do not show the protein-content, but this generally corresponds fairly closely to the cell-content, although it does not diminish quite as rapidly as the cell-content, and may be distinctly increased when the cell-content is normal.

I quote the following from the last article on the subject by Swift and Ellis:

> Each case presents a slightly different problem, and must be considered individually. Some respond much more rapidly than others, but the object in all should be to obtain a persistently normal cerebrospinal fluid. Of course, we cannot state with certainty that a normal cerebrospinal fluid assures that there will be no further progress of the degenerative process. All that we can say is as long as the cerebrospinal fluid gives evidence of a specific pathologic process in the central nervous system, and we have specific therapeutic measures which will remove that evidence, these measures should be applied. Only when the fluid becomes normal are we justified in discontinuing the treatment, and observations of the fluid should be continued so that at the first evidence of relapse treatment may be resumed. The method of intraspinous injection is not presented as a substitute for any of the accepted forms of treatment, but as an aid in attacking these severe infections. We feel that there is definite evidence that this form of treatment has a curative action on the syphilitic process, and that, therefore, its combination with intensive intravenous treatment is indicated where specially intensive treatment is required, as in rapidly advancing tabes or paresis, or where the disease has resisted other forms of treatment.

The opinion of those (all of the above-mentioned investigators, with the exception of Myerson) who entered into the discussion of this subject before the New York Neurological Society a few weeks ago was that we have in the intraspinous injections of salvarsanized serum the most promising treatment for tabes and paresis that has yet been recommended.

The Toronto.

THE AUTOSEROSALVARSAN TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM *

G. W. McCASKEY, A.M., M.D.
Professor of Medicine, Indiana University School of Medicine
FORT WAYNE, IND.

The recent demonstration of the fact that tabes and general paralysis are not parasyphilitic but actual syphilitic diseases—the lesions containing the *Spirochaeta pallida* as do other syphilitic lesions—has placed these diseases in the same group with the ordinary types of cerebrospinal syphilis, at least so far as etiology and therapeutics are concerned. There are, of course, certain well-defined pathologic variations dependent on the site, mode and avenue of attack of the chronic infection. The encephalitis of paresis, the predominating system lesion of the cord in tabes, and the characteristically bizarre pathology with the equally bizarre syndrome of the remaining groups of cases of cerebrospinal syphilis are perfectly well known, and we now understand certain familiar facts, as the frequent termination of tabes in paresis, and the common occurrence of intermediate cases, the classification of which was decidedly perplexing. They no longer need classification further than that implied in the scientific recognition of the accidental variations in the pathology produced by the luetic infection, together, of course, with the resulting variations in symptomatology.

Having established the syphilitic nature of tabes and paresis, we are still confronted with the clinical fact that these diseases, together with many of the other types of cerebrospinal syphilis, have until the present proved intractable to antisyphilitic treatment. At least one important reason for this has apparently been found in the inaccessibility of the subarachnoid lymph-space, including the general ventricular cavity. In spite of the fact that the terminal pial vascular network touches the boundaries of this space at every point, the main portal of entry appears to be through the chorioid plexus, probably for conservative reasons, perhaps to protect the delicate nervous structure which surrounds it from deleterious substances. If, however, as sometimes happens, an infection such as of the meningococcus or *Spirochaeta pallida* becomes entrenched in this area, the same mechanism which prevents the entrance of serum albumin, sugar, urea, ammonia, etc., which normally exist in the blood but do not enter the cerebrospinal fluid, also prevents the entrance of salvarsan, which would act as a perfectly effective trypanosomicide and rid the tissues of the spirochetes if it could only come in contact with them. This appears to be the main problem, although it will undoubtedly prove to be true in the types of cases under discussion—as Flexner has pointed out in a discussion of local infections in general—that there are more or less circumscribed areas with poor vascularization, which are difficult to reach even when attacked from both sides—that is, through the blood-stream by the intravenous method, and through the lymph-stream by the intraspinous method.

The credit of conceiving and perfecting an apparently safe and effective method of introducing a trypanosomicide into the subarachnoid lymph-space—one of the brilliant achievements of recent years—belongs to Swift and Ellis of the Rockefeller Institute. The idea was not entirely new, as the obvious advantage of introducing antisyphilitic remedies directly into the cerebrospinal fluid had occurred to others. Wechselmann and Marinesco[1] had independently injected small doses of salvarsan and neosalvarsan by lumbar puncture, but Swift and Ellis clearly showed by experiment on monkeys that it was too dangerous. Marinesco had even made intraspinal injection in syphilitics of serum from other patients who had been treated intravenously with salvarsan. This was not followed up by a perfected technic, although it involves the same principles, and under what could be called heteroserotherapy might still under certain conditions be the method of choice—almost of necessity.

TECHNIC

An intravenous injection of from 0.3 to 0.9 gm. of neosalvarsan is given, and one hour later about $1\frac{1}{2}$ ounces of blood withdrawn, allowed to stand until the serum separates, centrifugalized if necessary, and 12 c.c. of serum pipetted off. This is heated to 56 C. (132.8 F.) for thirty minutes, which activates the salvarsan, possibly by inactivating something else loosely combined with it, mixed with 18 c.c. of sterile normal salt solution, and injected by lumbar puncture after removing a few cubic centimeters of spinal fluid. In regard to the removal of spinal fluid I am inclined to think that a moderate increase of intraspinal pressure, if slowly and cautiously produced, hastens the diffusion of the neosalvarsan through the surrounding nerve structures, and that not much spinal fluid should, or at least needs to be, removed unless the pressure is quite high at the outset as determined by the flow. In a number of cases the injection has exceeded the fluid withdrawn by 20 c.c., and no symptoms were produced by the increased volume and presumably increased pressure.

---

[3] For a more detailed account of my results with the examination of the cerebrospinal fluid and Wassermann reaction see Rev. Neurol. and Psychiat., Edinb., August, 1913, p. 411.

* A Discussion Before the Twelfth District Medical Society, Fort Wayne, Ind., Nov. 5, 1913.

[1] Wechselmann and Marinesco: Quoted by Swift and Ellis. The Treatment of Syphilitic Affections of the Central Nervous System, with Especial Reference to the Use of Intraspinous Injections, Arch. Int. Med., September, 1913, p. 331.

My experience so far has been limited to seven cases. It is too soon to make a final report of these cases, but in view of the great importance of the subject, it has seemed to me worth while to state my conclusions, with brief outlines of the cases, hoping that it may encourage other clinicians to carry out what I believe to be by far the most important addition ever made to the therapeutics of cerebrospinal syphilis. Whether it will entirely annihilate the spirochetes, or whether there may still remain inaccessible foci of infection which will make recrudescence possible after the lapse of time, the future alone can determine. We are at least attacking the disease from a new angle, without hazard to the patient, and so far as I am concerned, I shall continue to advise autoserotherapy in all suitable cases of cerebrospinal syphilis, whatever form they may assume — paretic, tabetic, etc. — in the firm belief that many hitherto incurable cases may at least be relatively cured, while the cases which have heretofore been symptomatically cured, with subsequent recrudescence from latent foci, will be safer from relapse, if indeed it cannot be entirely prevented.

One of my cases (Case 3) under treatment illustrates, in what seems to me to be a very conclusive manner, the difficulty of reaching the infection of the cerebrospinal axis by the intravenous route. The patient had had the diagnosis of cerebrospinal syphilis confirmed two years ago at the Ann Arbor clinic. Since that time he had taken about twelve intravenous injections of salvarsan and later neosalvarsan. He had improved somewhat, but the nervous and mental symptoms had not improved and were possibly somewhat worse. He came under observation Oct. 15, 1913, at which time we found a negative Wassermann in the blood and a positive Wassermann in the spinal fluid. The case proves as clearly as anything can the difficulty of reaching the lymph-spaces of the cerebrospinal system, for after the serologic evidence of lues in the blood had been destroyed by repeated intravenous treatment extending over a long period of time, it was distinctly present in the spinal fluid. It should be stated, however, that the condition of the spinal fluid had materially improved under the intravenous treatment. At that time, as kindly reported to me by Dr. A. M. Barrett of the University of Michigan, there were 348 cells per cubic millimeter with a great increase in globulin, while at the time of my examination there were only twenty cells per cubic millimeter, but globulin was still present in excess, and, as stated above, the spinal fluid Wassermann was positive.

The case is mentioned here to illustrate the relative ineffectiveness of the intravenous method of treatment in some cases of cerebrospinal syphilis, and to uphold the view that salvarsan in the blood does not gain free access to the cerebrospinal fluid.

In another case of acute syphilitic insanity (Case 4) on a background of typical tabes—spinal myosis, loss of knee-jerk, Romberg symptom, paralysis of bladder, etc. — a positive Wassermann was found in both blood and spinal fluid. A full dose (0.9 gm.) of neosalvarsan was given intravenously, serum obtained as usual, and 12 c.c. in 40 per cent. solution given intraspinally.

In twenty-four hours the patient's general symptoms, especially the insanity, were greatly aggravated. He had to be held in bed one entire night, the type of insanity before this having been mild. This lasted thirty-six hours when the exacerbation disappeared, and since that time the psychosis has steadily improved. This case, with two or three others, has seemed to me to indicate that the destruction of myriads of spirochetes by the neosalvarsan had liberated excessive quantities of endogenous toxins, which temporarily aggravated the symptoms. Possibly, however, it was due to a direct action of the neosalvarsan on the tissues. Smaller initial doses should undoubtedly be given in such cases, and it is probably better in most cases to start with from 0.3 to 0.45 gm. of neosalvarsan.

The reaction following the intraspinal injection has rarely been pronounced. Occasionally a slight chill occurred, and sometimes pain in the back and limbs has lasted from a few hours to two or three days. In one such case the motor weakness of the lower extremities seemed to be somewhat greater for several days following the intraspinal injections. Improvement then began and has continued since.

I should like to mention here a case of petit mal (Case 7) with from five to ten attacks daily, beginning at about 35 years of age. Knowing that epilepsy at this late period might be luetic, I made a Wassermann and found it positive. Two intraspinal treatments were given with marked improvement (as recorded in the appended history). I made a Wassermann in the only other case of epilepsy developing late in life under immediate observation, but it was negative. I mention the case to suggest that in cases of epilepsy developing at 35 or 40, a Wassermann should be made as a routine, and if positive the autoserosalvarsan treatment should be tried intraspinally.

In conclusion, I only wish to say for the present that after giving twenty intraspinal injections of neosalvarsanized serum to seven patients over a period of about three months, I have seen in some cases remarkable improvement, and believe the method in careful hands, with perfect asepsis, and cautious dosage, to be devoid of danger, and to offer a new and entirely rational method of attack on the localized infection in cases of cerebrospinal syphilis.

Brief histories of the cases treated by this method, and notes of their progress up to date, are given below:

Case 1 (No. 746).—Man, aged 47, married, whose family and past histories are not remarkable, who denies venereal diseases, and whose wife has had no pregnancies, for 3 years has been nervous, has had marked tremor, and becomes confused easily. He has had four attacks in which speech was impaired and mentality markedly dulled. He gradually improved after each attack, but the general condition grew progressively worse until he gave up work ten months before examination. The patient had profuse watery discharge from the nose for some time, relieved by cauterization.

Physical examination showed a man fairly well developed and very well nourished, distinctly apathetic. Speech was slow and uncertain, and mentality obviously dull. There were marked coarse, convulsive movements of extremities and tremor in hands. Right pupil was twice the size of left; both were regular, and responded to light and distance. Knee-jerks were present, the right increased. Elbow-jerk was present on right side only. There was no clonus or Babinski, and no Romberg. Physical examination was otherwise negative. Wassermann of both blood and spinal fluid was positive.

Patient has had 4.5 gm. of neosalvarsan intravenously in five injections within three months and 60 c.c. of his own salvarsanized serum according to the technic previously outlined. Twice he has had mild reactions consisting of an exaggeration of the tremor and convulsive movements. There has been no other reaction. He has improved markedly so that he returned to work after the third injection and considers himself well. His wife notices, however, occasional evidences of mental impairment.

Case 2 (No. 881).—Woman, aged 55, married, with nothing remarkable in her family or past history, for several years has suffered with varied "nervous manifestations"—diplopia intermittent in character, numbness and paresthesias of right side, transient right-sided hemiplegia, subsequent motor weakness, occipital headaches, and finally two hard tumors of the skull. Wassermann one year before had been negative, probably because of mercurial treatment.

Physical examination showed marked internal strabismus of right eye, motor and sensory impairment of right side and two firm tumors several centimeters in diameter on skull in frontal and temporal regions of right side. Wassermann on blood was repeated and found positive.

Patient received three intravenous injections of 0.6, 0.9 and 0.9 gm., respectively, of neosalvarsan, the second being followed by an intraspinal injection of 12 c.c. of her salvarsanized serum. Marked febrile reaction with chills followed the intravenous injections and severe backache, with transient increase of motor weakness, and headache followed the intraspinal injection.

Nodules on skull have disappeared, vision is greatly improved, and sensory and motor paresis are much less marked.

Case 3 (No. 939).—Man, aged 44, married, childless, with family and past histories not remarkable, denying venereal disease, for two and a half years has been troubled by twitching of cheeks and lips, "stoppage of talk," loss of memory, and impaired locomotion. Speech is incoherent and disconnected. Patient has grandiose manner and mild delusions of same type. Diagnosis of lues had been made and patient had received from twelve to fourteen injections of salvarsan and neosalvarsan intravenously with some improvement.

Physical examination revealed nothing remarkable beyond what has been noted in the history except increased knee-jerks. Wassermann in the blood was negative and in the spinal fluid positive.

Patient has received 3.6 gm. of neosalvarsan intravenously in two months and 45 c.c. of his own salvarsanized serum intraspinally in four treatments without any reaction. His condition is greatly improved, the mental symptoms alone persisting though in lessened degree.

Case 4 (No. 963).—Man, aged 39, married, childless, with family history and past history not remarkable, who had gonorrhea but denied luetic infection, for two years had been known to have tabes and gonorrheal prostatitis, but had been able to attend to his business. Three weeks before, he began to show signs of mental disturbance—was distinctly melancholy and apathetic. Two weeks before, after a hard day's work, he developed a mild mania with fixed delusions. There was incontinence of urine.

Physical examination revealed the usual signs of tabes. Wassermann was positive in both blood and spinal fluid.

Patient was given 2.7 gm. of neosalvarsan intravenously and 28 c.c. of his own salvarsanized serum intraspinally in three treatments within a period of seven weeks. Marked psychic reaction followed the first injection but no other reaction was observed.

Patient's condition has improved in every way. Recently he had the best days in two years, but is still irritational at times. Locomotion is very good.

Case 5 (No. 949).—Man, aged 26, married, childless, with family history unimportant, admitting gonorrhea seven years ago and syphilis five years ago, suffered right hemiplegia six months ago. This improved for a time under treatment, but is now growing worse. Physical examination reveals only the hemiplegia. Wassermann of blood and spinal fluid is positive.

Patient received 2.4 gm. of neosalvarsan intravenously in three injections and 24 c.c. of his own salvarsanized serum in two intraspinal injections following the first two intravenous treatments. There was marked reaction causing increase of motor impairment of right side and some mental confusion after the intraspinal injections.

Patient has gained markedly in weight, speech has improved and locomotion has somewhat improved. He feels much better than at any time in last six months. He has acquired a fresh gonorrhea, or is suffering from a recrudescence of his former infection.

Case 6 (No. 961).—Woman, aged 58, married, mother of eleven children, with family and past histories not remarkable, for last eight months has noticed "numbness" of hands and feet, followed by marked loss of strength. Vision and hearing are impaired, dizziness, headache and nausea are present at times. Coordination is poor. She cannot walk.

Physical examination shows normal pupils, moderate Romberg, paresthesias but no anesthesias of arms and legs, knee-jerks present and equal, and no clonus or Babinski. Wassermann positive in blood and negative in spinal fluid. (Only 0.1 c.c. was used.) Urinalysis reveals a chronic nephritis.

Patient received 0.8 gm. of neosalvarsan intravenously and 24 c.c. of serum intraspinally in two injections. Mild reaction consisting of backache and nausea followed the first injection. Marked nausea of a week's duration but only mild backache followed the second.

Patient's sensory impairment has but slightly improved. Locomotion is much less difficult.

Case 7 (No. 63).—Man, aged 38, unmarried, denying any knowledge of syphilitic infection, for two years has had minor epileptic seizures gradually increasing in number up to from eight to twelve daily.

Physical examination revealed nothing remarkable. Patient had improved on bromids, but only for comparatively short periods. Wassermann of blood proved positive, of spinal fluid (0.1 c.c.) negative.

Patient received 1.8 gm. of neosalvarsan intravenously and 24 c.c. of salvarsanized serum intraspinally in two treatments. Temperature rose to 101.3 following first injection and patient complained of severe backache and occipital headache. Reaction following second injection was of same character but much less intense.

Number of seizures has been diminished to one slight attack daily with several successive days of complete freedom at times. General condition has distinctly improved. Patient volunteers statement that he feels better than for years.

PRESENT-DAY DANGER OF ROENTGEN-RAY BURNS AND HOW TO PREVENT THEM

G. E. PFAHLER, M.D.
PHILADELPHIA

The serious Roentgen burns that were produced during the early years of roentgenology made both patients and physicians cautious, and during the last eight or ten years the work has been done almost exclusively by specialists who have devoted their entire time and attention to roentgenology, and who have learned how to avoid burns, and yet to produce good results.

With rare exceptions during the past ten years, we have heard of no burns of patients, and the only thing that has made us remember any danger of Roentgen rays is the announcement of the death, from time to time, of some roentgenologist who had damaged himself early in the work.

The facts that these Roentgen ulcers in patients were produced during the early years of roentgenology, and that the damage done to roentgenologists occurred during these early years, have led the general profession to believe that danger in roentgenology has been eliminated, and that to-day every one and any one can use the Roentgen rays with safety. This is true only so far as those using the Roentgen rays have acquainted themselves with the dangers and learned to avoid them. A razor is a dangerous instrument in the hands of a child, but perfectly safe in the hands of those skilled in its use.

The marvelous advances that have been made in roentgenology, and the important field that it occupies to-day in diagnosis and treatment, have led to the exploitation of apparatus among the general profession by manufacturers who for the most part have in mind only sales, and therefore leave the physician under the impression that all he needs is the apparatus to do good work, and do it safely.

It is to be feared that the combination of enthusiasm for the use of the Roentgen rays and the false sense of safety will lead to disastrous results in the hands of untrained and unguarded physicians. Therefore it seems timely that a note of warning be sounded, for already there have come to my attention a number of serious Roentgen-ray burns produced recently by unskilled men, during single examinations. If this continues, much harm will be done to patients and physicians alike, and, secondarily, the specialty of roentgenology will be injured and its progress halted. It is a fact to-day that the Roentgen rays are absolutely harmless when properly used; that examinations can be made without the slightest injury to the patient, and that a roentgenologist probably can protect himself completely against its continuous and insidious evil influence. It is also a fact that the Roentgen rays as such are many times more dangerous to-day than they were ten years ago, because many times more powerful, and because the apparatus to-day is capable of a much larger output in a given time. Ten years ago, examinations were made with a current of from 1 to 5 milliamperes. To-day practically all examinations are made with from 10 to 100 milliamperes. Therefore it is easily seen that rays, as such, are ten times more dangerous to-day than they were ten years ago. They are made safe only because there is perhaps more than ten times as much knowledge concerning their use and dangers. This knowledge is at hand, is the property of the profession and is open to those who are willing to take the trouble to enlighten themselves. Besides the actual statement of facts such as can be found in literature, a certain amount of skill is needed, which can only be obtained by actual training or experience.

THE CAUSE OF ROENTGEN-RAY BURNS

The effect of the Roentgen rays on the tissues of the body depends on the quantity of rays absorbed, and the degree of sensibility of the tissues affected. The rays that pass through a tissue have practically no effect on it. Therefore it is the rays which are absorbed and do not pass through, which produce any beneficial or evil effect on the tissue. Therefore, the first essential is to be able to produce and judge the quality of the rays that will pass through a tissue. Most burns have been produced by the physician who lacks the ability to judge the penetration of the rays needed. As a result he is apt to use rays that are practically all absorbed in the superficial soft tissue, producing varying degrees of burns, depending on the quantity of rays. If he is using one of the modern powerful transformers, he can in a very short time produce enough rays to damage the soft tissues. For instance, one of the worst burns I have ever seen was produced by a physician while using one of our modern equipments, in an attempt to make an examination for stone in the kidney. His exposure was only two and a half minutes, and in this time he obtained no shadows on his plate. When the patient was seen five months after this injury, there remained an ulcer about 5 inches in diameter, which was excruciatingly painful and was showing no tendency to heal. In the hands of a skilful operator, with the same apparatus, a good picture of the kidney would have been obtained in from three to five seconds, and with absolutely no harm.

The damaging effects on patients and operators have been avoided in great part also during the past ten years, by the elimination of roentgenoscopic work.

The remarkable advances that have been made in the diagnosis of gastro-intestinal conditions by means of roentgenoscopy during the past five years have created a wave of enthusiasm for this class of work, and has led many into the use of the Roentgen rays for this purpose even though they do not take the trouble to make roentgenograms. This class of physicians is likewise apt not to take the trouble to learn the underlying principles governing the use of the Roentgen rays, and as a result they are apt to think that because they do not see a thing well, they are not using quite enough current. Current is, therefore, crowded into their tube, and while they do see a little better for the time being, they often produce a tremendous amount of soft rays, which are being absorbed by the soft tissues of the patients and themselves, which result in a dermatitis in both the patient and the operator. An illustration of this came to my attention recently. Two physicians were examining a forearm for a foreign body by means of the roentgenoscope. The single examination was followed by a well-marked dermatitis on the hands and forearms of the two physicians, and a Roentgen ulcer on the forearm of the patient that is not yet healed, several months after the injury. In the hands of a skilful operator a foreign body such as this can be localized and removed under the direction of roentgenoscopy, and do neither the patient nor the operator harm.

In roentgenoscopy it is not necessary to use a great amount of current. Most of my roentgenoscopy is done with 1 milliampere. In all roentgenoscopy both the time and the quantity of current should be kept at the minimum.

HOW TO AVOID ROENTGEN BURNS DURING EXAMINATIONS

In the avoidance of burns one must first keep in mind the principles governing the cause of the burns:

1. To use as small a quantity of rays as is consistent with the examination.

2. To use a quality of rays that will penetrate the tissues, and not be entirely absorbed by the soft tissues. One can learn to judge the penetration by frequent use of the penetrometer and by the making of many roentgenograms.

3. To make every examination as short as is possible, thereby lessening the total amount of rays to be absorbed.
4. To use intensifying screens when practicable.
5. To use filters for the elimination of the softer rays.
6. To confine the rays to the part actually under examination.

Burns of the operator may be avoided: (1) by keeping entirely out of the field of rays, by working from an adjoining room with lead-lined walls between, or by the use of lead-lined cabinets; (2) by confining the rays about the tube so that the only way of exit is through the aperture made for the examination of the patient; (3) by means of protecting shields, aprons, gloves, masks, etc. In fact, all these should be combined.

Burns during Roentgen therapy may be avoided, (1) by following the same general principles referred to in diagnosis; (2) by measuring each dose given and never exceeding the limit of skin toleration as indicated by the dose meter; (3) by allowing an interval of three weeks between the repetitions of the dose on any particular area of skin; (4) by the use of more filtration than would be used in diagnostic work; (5) by keeping in mind the fact that epithelium and glandular tissue are more sensitive than other tissue to the rays; (6) by avoiding any other form of irritation on the skin treated, such as counterirritation, high-frequency currents, liniments, stimulating ointments, antiseptics, etc.

The details necessary in carrying out the foregoing principles will vary with the individual operator and his circumstances, but they should receive the most careful attention. I believe that roentgenology is more distinctly a specialty than any other, because to master it one must be a good physician, must have a good general knowledge of pathology both in general medicine and the specialties, must have a large equipment, must give much time to the mastery of details, and must always be cautious.

1321 Spruce Street.

TREATMENT OF TETANUS BY THE "RATIONAL" METHOD OF ASHHURST AND JOHN

THE DEVELOPMENT OF SUPPURATIVE SERUM (ASEPTIC) MENINGITIS FOLLOWING THE INTRASPINAL INJECTION OF TETANUS ANTITOXIN; WITH REPORT OF A CASE *

WALTER V. BREM, M.D.
LOS ANGELES

In a recent article on the treatment of tetanus, Ashhurst and John[1] conclude that the rational use of tetanus antitoxin consists in (1) the intraneural injection of antitoxin; (2) the intraspinal injection; (3) the intravenous injection, and (4) the infiltration of the tissues about the site of the injury.

The quantity used should be very much greater than the quantity that has usually been given heretofore by the subcutaneous route. In one of their cases in which the subcutaneous route was used, 224,000 units were administered in three days. But such an enormous quantity is not demanded when the intraneural and intraspinal routes are chosen. These authors feel that the outlook for patients with tetanus is much brighter now since the development of this method of administering antitoxin, and that the old view, that antitoxin is of no avail after the symptoms of tetanus have developed, must be abandoned.

In 1910, at Colon Hospital, Canal Zone, I treated four cases of tetanus by intraneural, intravenous and subcutaneous injections of antitoxin, and used chlorbutanol (chloretone) and morphin as sedatives. These cases are reported in detail by Hill.[2]

One of these patients, whose case was a severe one with a ten-day incubation period, recovered. From this patient the infecting tetanus bacillus was passed through a series of guinea-pigs. The last two of these pigs, after local tetanus was well developed, were treated by postorbital injection of 1 c.c. of tetanus antitoxin. One pig recovered, and the other seemed to be recovering when it was accidentally killed by a subcutaneous injection of chlorbutanol in alcohol. Smears made from the wounds showed Gram-positive bacilli that appeared to be in all stages of degeneration. This was shown by great swelling and granulation of the bacilli, atypical shapes, and the absence of spore formation. Furthermore, the splinter which had been removed from the patient's wound and had been used in successive inoculations, failed to infect another pig when removed from the last-treated animal. The dosage used in treating these animals postorbitally was equivalent to about 30,000 units in an adult man.

I have not had an opportunity since then to examine the results that I obtained in the treatment of these guinea-pigs, but I felt the results suggestive enough to warrant the use of intraspinal injections in future cases of tetanus. I was ready, therefore, to accept the views of Ashhurst and John when their article appeared, and shortly afterward I had an opportunity to apply, successfully, their methods to the treatment of a patient with cephalic tetanus, which developed after a six-day incubation period.

REPORT OF CASE

Injury by baseball on upper lip; six-day incubation period; gradual onset; intraneural, intraspinal and intravenous injection of 98,000 units of tetanus antitoxin and infiltration of lip about the injury; suppurative serum (aseptic) meningitis following intraspinal injection of antitoxin; rapid recovery.

The case occurred in the private practice of Dr. P. Newmark of Los Angeles, who called me in consultation and requested me to treat the patient. I wish to thank Dr. Newmark here for permitting me to publish the case-report, and for his courtesy and encouragement during the trying days of the treatment.

History.—The patient was a robust man aged 21. He had been struck on the left side of the upper lip by a baseball on Saturday, July 12, 1913. The blow caused an abrasion of the skin, and the mucous surface of the lip was cut by the impact against a tooth. The skin abrasion was treated with hydrogen peroxid by the patient's mother several hours after the injury occurred. Healing of the wounds, both inside and outside, was rapid. On Friday evening, July 18, the patient's teeth clamped down tightly on a cigar that he had begun to smoke, and he noticed that his jaws were stiff. His jaws were stiffer on Saturday, the 19th, and he began to feel pain in his back. He called on Dr. Newmark on this date, but not finding him he did not see him until Sunday afternoon, July 20, when the back was more painful and was stiff and the jaws were about as stiff as on the day before. The patient was taking only liquid nourishment. On Sunday evening I saw the patient with Dr. Newmark, who suspected tetanus.

[2] Hill, E. W.: Tetanus, Arch. Int. Med., Dec., 1911, p. 747.

Physical Examination.—July 20, 8 p. m.: The patient was sitting up in bed, smiling and talking. His speech was somewhat thick and his jaws seemed stiff. He was a well-nourished, robust young man. The teeth could be separated only 1 cm. There was a slightly indurated area on the left side of the upper lip, and a scar on the corresponding mucous surface. The throat was not sore, and there were no tender teeth or swollen gums, and no enlargement of the cervical lymph-nodes. Examination of the heart, lungs and abdominal viscera revealed nothing abnormal. The back was stiff, and flexion of the body caused pain. The neck was not stiff, and the chin could be lowered almost to the sternum.

Reflexes: The patellar reflexes were much exaggerated; there was no ankle-clonus; Kernig's sign was not present though the hamstring tendons were quite tense when the leg was extended; the superficial and deep abdominal reflexes were exaggerated, and also the cremasteric reflex. Reflexes of the upper extremities were about normal.

At this time 8,000 units of tetanus antitoxin were given subcutaneously.

July 21, 8 p. m.: Dr. H. G. Brainerd was called in consultation and he confirmed the diagnosis of tetanus. The patient's jaws were perhaps slightly stiffer, his neck muscles were growing stiff, his back was slightly bent backward and his chest thrown out, giving a pouter-pigeon effect. The reflexes were increased more than on the 20th, and the biceps reflex was exaggerated. There had been no convulsions. The patient was removed to the hospital and prepared for operation for the intraneural injection of the left facial nerve. Before the operation he complained of great pain in his back and he showed definite opisthotonic spasms.

The left facial nerve was exposed by Dr. F. S. Ray, who cut down through the left parotid gland. An unknown, but small, quantity of tetanus antitoxin was injected into the sheath of the nerve, and the surrounding tissues were infiltrated. A small drain was left in the wound. A lumbar puncture was then made and about 20 c.c. of cerebrospinal fluid were removed and 13,000 units of antitoxin injected; 10,000 units were then given intravenously, and the site of the injury on the lip was infiltrated with 2,000 units.

The cerebrospinal fluid was clear, pressure 170 mm. in a capillary tube, no cells were seen in 1 c.mm., the butyric acid test was doubtful (reaction ±), with 0.2 c.c. Wassermann test negative. Five c.c. of the fluid were injected subcutaneously into a guinea-pig, which remained well.

July 22, 9 a. m.: The patient vomited twice after the operation. The temperature was 101.4, the pulse 84. There was severe headache and backache. The jaws were opened less widely, the back was stiff and there was a tendency to opisthotonos. Sixty grains of chlorbutanol in olive-oil by rectum, and ¼ grain morphin hypodermically were ordered according as circumstances might require.

3 p. m.: Condition was the same. Kernig's sign was marked. Tetanus antitoxin, 20,000 units intravenously and 10,000 units intraspinally, was injected.

Cerebrospinal Fluid: Fifteen c.c. of turbid, whitish fluid were obtained. Pressure was 210 mm. The cells numbered 3,940 per cubic millimeter; polymorphonuclear neutrophils predominated, but there were many lymphocytes and endothelial cells. Stained smears from the centrifugalized sediment showed no bacteria. Aerobic and anaerobic cultures on blood-agar and hydrocele-agar remained sterile. Aerobic and anaerobic cultures from Cutter's and Parke, Davis & Co.'s antitetanus serums remained sterile.

July 23, 9 a. m.: Patient's condition was about the same as yesterday. The signs of meningitis were well marked, and almost obscured the signs of tetanus. Temperature was 101.8, pulse from 40 to 60; there was severe headache and backache, the neck was stiff, Kernig's sign was marked; chest protruded, abdominal and spinal muscles were hard, spine curved backward. There was facial paralysis on left. The operative wound was clean.

3 p. m.: Tetanus antitoxin, 10,000 units, was given intravenously. By lumbar puncture about 25 c.c. of turbid, whitish fluid were obtained. It was more cloudy than on yesterday. Pressure was 340 + mm. The cells showed great predominance of polymorphonuclears and fewer lymphocytes and endothelial cells than on yesterday. Smears and cultures (aerobic and anaerobic on hydrocele-agar) were negative for organisms.

July 24, 9 a. m.: Patient's condition was improved, headache was not so severe, jaws opened more widely, neck and back were not so stiff, patellar reflexes were still exaggerated, Kernig's sign was marked, and there was no ankle-clonus.

3 p. m.: Tetanus antitoxin, 10,000 units, was given intravenously. By lumbar puncture about 20 c.c. of fluid were obtained. It was less turbid than on yesterday; pressure 300 mm. Cell-count showed 1,020 per cubic millimeter, polymorphonuclears predominating; there were only a few lymphocytes and endothelial cells. Smears were negative for organisms. Cultures (aerobic and anaerobic on hydrocele-agar) remained sterile.

July 25, 9 a. m.: Patient's condition was much improved, temperature was normal, there was no headache, neck and back were much less stiff, jaws opened widely, left facial paralysis was gradually clearing up, and Kernig's sign was present but less marked.

5 p. m.: Tetanus antitoxin, 10,000 units, was given intravenously. No lumbar puncture was made.

July 26, 9 a. m.: Condition was greatly improved. Temperature was normal, pulse 72. There was no headache; jaws were widely opened; Kernig's sign was present but less pronounced, and patellar reflexes were slightly exaggerated. The patient was bright and felt well and hungry. His bowels had moved well, but he had not been able to void urine voluntarily since the operation and had had to be catheterized. No antitoxin was given to-day and no lumbar puncture made.

July 28, 9 a. m.: Condition was excellent, temperature and pulse normal, no headache, appetite good, bowels normal, urination spontaneous, mouth opened widely, facial paralysis was improving, patellar reflexes were slightly exaggerated, Kernig's sign was present when thigh was flexed on abdomen, but negative when flexed to a right angle. Patient was discharged from the hospital.

Subsequent History.—The patient convalesced rapidly, though his reflexes remained slightly exaggerated for about two weeks. The facial paralysis had almost disappeared three weeks after the operation. During convalescence the skin over the left parotid gland puffed up with parotid secretion, which formed a fluctuating mass without redness, pain or local heat. Dr. Ray aspirated the fluid with a hypodermic syringe several times and put on a dressing with slight pressure. This quickly checked the secretion and healing was complete.

Summary.—Young man of 21 years, cephalic tetanus, six days' incubation period, gradual onset, treatment begun eight days after injury and two days after onset of symptoms; intraneural injection of unknown but small quantity of tetanus antitoxin into left facial nerve; intraspinal injections of 23,000 units; intravenous injections of 60,000 units; subcutaneous injection of 8,000 units; infiltration of tissues about site of injury with 2,000 units, total quantity of antitoxin 98,000 units; development of meningitis within six hours after first intraspinal injection, purulent fluid sterile by microscopic and cultural aerobic and anaerobic examination; rapid recovery from tetanus and meningitis.

DISCUSSION

Cephalic tetanus is a very fatal type of the disease, and the outlook is extremely grave in any type with an incubation period of only six days, the mortality being from 60 to 80 per cent. In the case here reported the type of the disease and the incubation period would indicate a grave prognosis, and one is tempted to grow enthusiastic over the method of treatment that was associated with such a prompt recovery. But it must be remembered that the onset of symptoms in the case was very gradual, which is a favorable prognostic sign, and that there was some chance of the patient's recovery without the antitoxin. Nevertheless, the recovery of the patient, and especially the very rapid recovery, gives great encouragement for the future treatment of tetanus along the lines suggested by Ashhurst and John.

A phenomenon of almost as great interest as the recovery under the treatment given was the development of a true suppurative meningitis, with all the clinical signs of meningitis, following the intraspinal injection of tetanus antitoxin. This was proved to be, without doubt, of non-bacterial origin bv the microscopic examination of the cerebrospinal fluid, by aerobic and anaerobic cultures, and by the recovery of the patient. The reaction did not appear to be due to hypersensitiveness to the horse-serum, for the patient had never before this illness been given antitoxin of any kind, he was not an asthmatic, nor did he have any reaction when given 8,000 units subcutaneously of tetanus antitoxin the night before the intraspinal injection.

In the literature that I have been able to examine, the only references to aseptic meningitis following the intraspinal injection of serum are made by Sophian[3] and by Sladen.[4] Sophian says:

> In this group (aseptic meningitis) may be mentioned cases showing clear fluid on lumbar puncture but with clinical symptoms of meningitis sufficiently suspicious to warrant the intraspinal administration of serum. Such cases will frequently give a turbid, purulent, sterile fluid at a later puncture also as a result of the reaction set up by the serum. No damage, however, results in such cases, as the fluid clears up in a few days with no after-effects.

The proof is not absolute in this group of cases that the purulent meningitis was a reaction to the serum, for before the serum was given the patients had "clinical symptoms of meningitis sufficiently suspicious to warrant the intraspinal administration of serum."

When the cerebrospinal fluid is examined very early in meningococcus meningitis it may not be purulent and may show no meningococci. If serum is injected at this time, the fluid may still become purulent and yet the serum may prevent the appearance of meningococci. The cases spoken of by Sophian do not present, therefore, conclusive evidence of a serum meningitis, but they are very suggestive.

Sladen, in discussing the effect of the injection of antimeningitis serum on the spinal fluid, says:

> In every case there is a very constant, positive chemotaxis for polymorphonuclear leukocytes in the spinal fluid. This has been observed in one case of influenzal meningitis. In six cases of tuberculous meningitis the clear spinal fluid with predominating small mononuclear cells has become clouded with polymorphonuclears after serum, and the small mononuclear cells have totally disappeared.

These observations of Sophian and Sladen and my own case seem to demonstrate conclusively that the introduction of a foreign serum into the spinal canal may cause a reaction that presents all the clinical and pathologic evidences of an acute suppurative meningitis, except that no bacteria can be demonstrated in the purulent cerebrospinal fluid. It seems plausible, furthermore, that the exacerbations frequently following the intraspinal injections of serum in meningococcus meningitis are due to the reaction to the horse-serum, and that it is independent of the condition of hypersensitiveness.

These facts are of the greatest importance to those who are called on to inject substances intraspinally. This route for therapeutic measures is being used more and more frequently, and it is probable that many instances of serum meningitis will be seen. It will be interesting to know whether or not the intraspinal injection of salvarsanized human serum by the method of Swift and Ellis[5] may sometimes stimulate the reaction. These authors[6] report a great increase of cells in the cerebrospinal fluid of normal monkeys after the intraspinal injection of salvarsanized monkey-serum, and that the cells causing the increase were chiefly polymorphonuclears. In one instance the number reached over 4,000. I have seen an increase of cells in two patients two weeks after an intraspinal injection of salvarsanized serum, and in one case there were 22 per cent. of polymorphonuclears. It is probable that the number of cells and the percentage of polymorphonuclears would have been much greater if the fluid had been examined shortly after treatment.

When a meningitis reaction does occur it may be very alarming, especially if one is not cognizant of the fact that such a purulent meningitis may be sterile and caused entirely by the serum. I myself was not aware of it at the time my case occurred, and I felt that I had infected the patient during the intraspinal injection. Happily, this was not true, and I trust that the publication of the case-report may save some one else the stress of feeling that he has superimposed a bacterial meningitis on a case of tetanus.

Note.—Since submitting this report for publication I have found a report by J. A. Sicard, ("Serous Meningitis and Anaphylaxis after Spinal Serotherapy," Presse Méd., xviii, No. 92; abstr. The Journal A. M. A., Jan. 7, 1911, p. 78) in which he states that he encountered the reaction from the intraspinal injection of antimeningitis serum in nervous and mental cases. After the injection these patients developed fever, headache, nausea a suggestion of Kernig's sign, and pains in the legs. The cerebrospinal fluid became turbid and showed a polynucleosis gradually yielding to lymphocytosis. Sicard suggests that in acute meningitis the symptoms have masked those due to the serum reaction, which explains why the latter have not been recognized before. He states that the reaction has nothing to do with anaphylaxis as it occurs with the first injection.

A NEW AND LOGICAL TREATMENT FOR ALCOHOLISM

A PRELIMINARY REPORT

B. L. SPITZIG, M.D.
CLEVELAND

Personal observation of the effects of the treatment proposed in this communication extends over a period of two years. Although this study is too incomplete to determine the permanency of the therapy advocated, yet the progress of the limited subjects treated is so unassailable that I consider this field for investigation worthy of proposal to others for more extended research.

The type of patient governs largely the success or failure of this treatment. The derelict who has no ambition to cooperate with his physician is a poor subject for trial. The best results are obtainable among the intelligent class who have sufficient interests at stake to make their recovery a matter of vital importance to society at large. After reclamation these persons possess sufficient momentum to persevere in their treatment and to guard themselves against a reversion to former conditions.

[6] Ellis, A. W. M., and Swift, H. F.: The Effect of Intraspinous Injections of Salvarsan and Neosalvarsan in Monkeys, Jour. Exper. Med., 1913, xviii, 428.

The study of the habits and characteristics of the alcoholic in eating and drinking had always been a source of great personal interest to me, and the following observations seemed particularly pregnant: Many tipplers begin at an age when boyish habits have yielded to those of the man. At maturity the demand for carbohydrates is gradually lessened. Usually the adolescent loses his craving for sweets and begins to indulge in alcoholic beverages. As the supply of alcohol is increased the desire for sugars is correspondingly diminished until a time when alcohol is taken in preference to carbohydrates. In alcoholism, then, there is often a positive aversion for sugar. This history of certain characteristics in the chronic alcoholic is quite general. He uses no sugar in coffee and tea and cares little for pastries and starchy products. Stimulating food, rich in condiments, is his mainstay and his appetite for stimulating drink is thereby increased. The body, in consequence, receives a minimum of sugar and becomes accustomed to more alcohol, which has now replaced the former. This is evident from a study of the relationship existing between the type of beverage used and the degree of the resultant alcoholism. The moderate drinker often utilizes a sweetened product and is satisfied to indulge in moderation. He assimilates both sugar and alcohol and his thirst is stilled with less drink. The confirmed alcoholic cares for no sugar and absorbs greater quantities of unsweetened alcohol to satisfy his bodily economy.

The chemical relation of carbohydrates to alcohol is significant. Dextrose is convertible to carbon dioxid and ethyl alcohol. The combination of carbon, hydrogen and oxygen makes for increased nutrition whether it be derived from alcohol or indirectly from sugars and starches. The human organism when deprived of sufficient sugar seems of necessity to demand an increased supply of alcohol. Conversely, when the body is satiated with alcohol, it has little need for carbohydrates.

TREATMENT

Chronic alcoholism is treated on the basis of the foregoing proposition—the supply of alcohol is diminished and sugars are increased. This renders the early weeks of treatment a time during which the perversion is easily remedied. Many former systems have failed in that alcohol was suddenly withheld and nothing substituted to satisfy the craving. Narcotics merely benumb the alcoholic desire, but seldom accomplish a permanent cure. The demand for alcohol in the perverted metabolic state of the alcoholic is not mental alone, but physical or rather physicochemical. When the body-cells are supplied with a physiologic balance of carbohydrates there is no further demand for alcohol.

At the inception of treatment the diet is modified to contain an abundance of sugar. Cereals with cane-sugar, sweet fruits, pastries, chocolates and ice-cream are advised. In some cases, owing to a distaste for sugars, this change must be gradual to prevent rebellion. Here lactose is used, a dram every two hours, given in the form of a medicinal powder to encourage the psychic effect. Later, as the demand for alcohol is palliated, ordinary sugars are taken with avidity.

The use of alcohol is generally interrupted by degrees. Cathartics and diuretics are advised to remove the accumulated poison and prevent an acute intoxication. The weaning from alcohol is accomplished by the substitution of highly sugared liquors, which are rapidly reduced in quantity. Toddies, juleps and sweet wines yield the best results. A sweetened liquor relieves excessive craving in from one to four weeks. The average alcoholic omits alcohol after from three to five days, but a premature withdrawal is to be avoided.

Combinations of capsicum and nux vomica are sometimes necessary during the first week to allay the gastritis. Soporifics are used to soothe the nervous manifestations. After self-confidence is reestablished all medication is interrupted and the sugars are gradually decreased. With care in studying the carbohydrate-tolerance, glycosuria can usually be avoided.

CONCLUSION

The demand for alcohol has been ascribed in the past to a psychic defect. Pledges have been broken and weakened will-power has been considered the causative factor. In virtue of these studies it appears that the alcoholic suffers his relapses through physicochemical disturbances. A clearer understanding of the needs of human economy has effected much toward obviating the discouraging results of the past.

ADMINISTRATIVE AND PROPHYLACTIC MEASURES AGAINST ALCOHOLISM

ALFRED GORDON, M.D.
PHILADELPHIA

In view of the well-demonstrated effect of alcoholism on the physical and mental health of the individual at an early age and in adult life, and also of the particularly disastrous influence on the successive generations of offspring of alcoholized parents, the question naturally arises as to the responsibility of the community as well as of its individual members in the matter. The alarmingly increased number of victims of alcoholism calls for very serious thought directed toward preventive measures.

It must be borne in mind that an alcoholic subject is harmful to himself through his lowered physical and mental status; to the community at present through his tendency to commit criminal acts, and to society for the future because his descendants may be degenerate through several generations. Can society protect itself by creating laws against alcoholism?

In my opinion, legislative acts can be of assistance only in one respect, namely, by largely limiting the production of alcohol in preventing the unlimited manufacture of alcoholic beverages. A very high tariff and high taxes will naturally restrict this industry considerably, and render the beverages less accessible to persons of ordinary means. But it must be borne in mind that such legislative measures are not to be expected in view of the fact that laws are usually enacted by legislators, some of whom are financially interested in the industry.

On the other hand, laws designed to suppress alcoholism merely by imprisonment or other punishment are entirely inefficacious, because they purpose to remove the effect but not the cause. One who is addicted to the repeated or continuous abuse of alcohol belongs in the domain of morbid psychology. Whoever analyzes the psychic processes which lead to alcoholism must admit that they include profound changes in the mentality, deep lacunae in the cerebral organization, so that one thus affected loses his inhibition power, hence acts on impulse, and therefore is in need of medical attention, but not of a prison.

Ordinarily, the alcoholics are sent either to prison or to asylums for the insane, according to the degree of individual responsibility determined by the committing judge. For criminal acts committed during a phase of delirium the alcoholic must be considered irresponsible, and he therefore falls into the category of the insane. An asylum is the only place for such.

If alcoholics have not reached the condition of actual dementia, they frequently recover from acute attacks or, more frequently, recover sufficiently to be considered responsible. The law, of course, requires prompt removal from the asylum. In the majority of cases the alcoholic is a recidivist. Return to alcoholic excesses usually occurs and with it a return to criminal acts is a great possibility. The recommitment to asylum is inevitable. Thus certain persons spend a considerable time between the saloon and the insane asylum. This is the common experience of those who have to deal with this class of cases. The insufficiency and inadequacy of our laws concerning the freedom of chronic alcoholics is self-evident.

Apparent recovery from individual attacks does not constitute a genuine recovery from deeply seated intoxication. The elimination of drink for a period of two or three weeks does not conduce complete recovery from an old intoxication, which perceptibly affected the power of thinking and of inhibition. Considerable time is required to accomplish this, and if in a chronic subject acute symptoms quickly subside, the likelihood is great that the condition will recur. From a medical point of view, a prolonged detention is indispensable in such cases, not only for the benefit of the patient, but also and particularly for the benefit of society in general.

The protection of the community is of paramount importance. As the detention of chronic alcoholics in insane asylums may be detrimental to them after they recover from the acute symptoms, and, on the other hand, liberty is decidedly injurious to them and dangerous to society, which claims protection, the creation of special institutions is logically indicated.

A hospital exclusively for inebriates is a necessity. It should possess the power of judicial as well as of medical authority. It is urgent that alcoholics with, as well as recidivists without, a criminal record be placed where they may receive medical treatment. They should not be permitted to leave until the medical authority, after prolonged observation and treatment, finds that it will be safe to set them at liberty. Special laws are of course necessary to regulate the authority of the medical officer in charge of the institution. To avoid arbitrary action and abuse in cases of prolonged detention a judicial officer should join the medical staff. Thus an impartial and scientific decision will be reached in cases in which the legality of detention is questioned.

The public should be instructed as to the utility of such an institution. It should be viewed from a purely humanitarian point of view. It should be regarded as a hospital in which alcoholics as diseased individuals receive medical treatment. It is not only the immediate alcoholic excess that requires medical attention, but also and chiefly the underlying make-up of the person in whom alcoholism is merely incidental. To such an institution should be admitted all alcoholics irrespective of the degree of intoxication. Those whose alcoholic history is but brief are susceptible of complete recovery. Inveterate alcoholics and those with criminal records should be detained indefinitely. Thus both the individual and society will be protected. The alcoholic will be deprived of his liberty, which otherwise he would use to injure others, and at the same time he will receive special care and humane attention to a condition which renders him irresponsible. Besides, an institution of this nature will relieve the prisons of a number of alcoholics, whose irresponsible acts committed during an acute outbreak led them there and thus an important medicolegal question will be solved. It will relieve the insane asylums, whose overcrowded condition has been a matter of great concern. Moreover, an inveterate alcoholic cannot recover in an ordinary asylum. The rules applied to insane individuals cannot be applied to alcoholics, who rapidly recover their intelligence to a large extent. The continuous contact of delusional persons with alcoholics is injurious to both. The latter are frequently a cause of disturbance in an institution for the insane.

The medicolegal advantage of a special institution for inebriates is of great importance. The detention of an alcoholic presents some difficulty in regard to the question of personal liberty. But in order to render a special institution for inebriates useful and powerful in its struggle against alcoholism, in order that the community should derive the greatest possible benefit in its own protection, it will be necessary that the patient be detained for a period so prolonged that no doubt is left as to the recovery in the unprejudiced mind of the medical authority. Detention of an alcoholic among other alcoholics beyond the time when he has apparently recovered his mentality is not at all prejudicial to him, while his detention among the insane under the same circumstances is, beside being injurious to him, decidedly unjust.

To sum up, a special institution for inebriates has for its purpose the treatment and cure of alcoholic patients whose mental disturbances are the result solely of repeated or continuous use of alcohol; also the indefinite detention of alcoholic persons whose actions have proved them to be dangerous to the community. It is self-understood that actual dements, whose dementia is the result of old alcoholism or insane persons whose preexisting mental disorder may be modified by the occasional use of alcohol belong to insane asylums, but not to special institutions for inebriates.

As to the management of these special institutions and of their inmates, the following main principles appear to be of some practical value:

1. Patients should be classed and grouped according to the degree of intoxication, the presence or non-presence of delirious, delusional or hallucinatory phenomena, the chronicity of the intoxication and the existence or nonexistence of criminal tendencies.

2. The use of alcohol must be absolutely forbidden to all inhabitants of the institution.

3. The greatest effort should be made toward improvement of the general health by appropriate dietetic and hygienic measures.

4. Since physical labor, to which every patient free from delirious condition should be accustomed, is an excellent and in fact indispensable adjuvant to diet and hygiene, the spirit for work should be cultivated when-

ever possible. It is one of the most useful methods in treating those who have defective cerebral inhibition. Systematized labor properly directed will accomplish a double purpose. It will first of all encourage those patients who have sufficiently recovered to realize that the institution is managed from a humanitarian point of view; namely, to assist them in their present condition and after their return to their homes. In the next place, the institution from such an arrangement may become self-supporting. Social service is a useful adjuvant to such a plan. It will facilitate the return of the subject to a normal life by procuring him work, by properly advising him and by developing in him the spirit of hopefulness and initiation.

At the beginning of this article it was shown what preventive legislation may do. Reduction of the number of saloons may help to a certain extent, but such a procedure is considerably less valuable than reducing the production of alcoholic beverages, as the existence and increase of saloons are the result of a demand for alcoholic beverages. As legislation in either direction is intimately associated with political agitation, our endeavors in this respect will naturally fail. The increase of saloons does not increase the number of drinkers; it is the demand for alcohol that increases the number of saloons. It behooves us, therefore, to combat and endeavor to remove the morbid desire for alcohol. The principle of diminution of the number of saloons, however, should be adopted.

A more useful measure for decreasing and preventing alcoholism is propaganda in its broadest sense. The moral and intellectual influence of various antialcoholic societies is beneficial. The good they do cannot be sufficiently appreciated. Moral persuasion and conviction is most efficacious in that direction. The widest publicity concerning the effect of alcohol on physical and mental health should be considered as vital. The public should read and see the pernicious consequences of alcoholism. Lectures and clinics should be systematically organized and actual demonstrations given. The public should be invited to visit particularly institutions for the feeble-minded where they could see for themselves specimens of humanity brought into the world by parents whose alcoholic excesses have thrown on the community a useless burden. Imbeciles, idiots, and those otherwise mentally deficient, epileptics and children with all sorts of morphologic abnormalities, result from parental acquired diseases or pernicious habits of which alcoholism is one of the most conspicuous.

Propaganda against alcoholism should be particularly applied to young persons and children. The rôle of the physician is here indicated. It is he who comes in contact with families. As counselor in medical and hygienic matters he can use his great influence in various circles. Considered as a man of knowledge and experience, he will be listened to. He can prevent parents from giving children their first taste of drink. It is he who controls the diet and hygiene of children. It is to him that the mother addresses herself for advice as to the habits of her children.

Next to the physician is the children's teacher. But the teacher himself must be well informed as to the nature and dangers of alcoholism. He should have taken, before he is permitted to instruct, a special course in social hygiene in which the effects of alcoholism should occupy a prominent place. Such a course should be given in schools and colleges, and the instruction should be not only theoretical but also practical. It is necessary that every youth leaving school should possess a fundamental knowledge of the effect of alcohol on tissues, organs, the nervous system, the mentality and the offspring. From a tender age the child should be thoroughly imbued with the idea that alcohol is one of the most obnoxious and dangerous poisons. It is the knowledge of what is true, useful and indispensable in life that presents the most powerful weapon against the acquirement of pernicious habits or diseases. Imparting this knowledge constitutes real scientific prophylaxy.

The public at large should be familiarized with the fact that one of the threatening features of alcoholism is depopulation not only quantitatively, but also qualitatively. It leads to a degeneration of both the individual and the species. It produces a slow and progressive individual deterioration and an intellectual and physical sterility of the race.

THE DOSAGE OF COCAIN AND OTHER DRUGS USED FOR PRODUCING LOCAL SURGICAL ANESTHESIA

ALBERT H. MILLER, M.D.
PROVIDENCE, R. I.

Local surgical anesthetics are applied in three ways: externally to mucous membranes, hypodermically in the region to be operated on or in the locality of the nerve-trunks innervating the region of the operation, and by injection into the spinal canal. The effect aimed at in using local surgical anesthetics is local. Unfortunately, these drugs have also a general effect, which may be produced whether the drugs are administered externally to mucous membranes, hypodermically, or by injection into the spinal canal. The general effect depends on the amount of the drug which is administered, a greater effect being produced by a larger amount of the drug without regard to the strength or weakness of the solution in which it may be administered.

The toxicity of cocain is the objection to its general use as a local surgical anesthetic. The drugs which have been introduced as substitutes for cocain are less toxic, but cannot be considered as entirely safe. The extension of the idea that these drugs are safe in unlimited dose is bound to result in disaster.

The dosage of cocain is indicated exactly in the United States Pharmacopeia. The proper dose of the substitutes for cocain is generally unindicated and impossible to learn from medical literature. The dosage of these drugs is given in the literature furnished by the manufacturers in strength of solution, the inference being that any amount of a solution of that strength may be employed with safety. The dosage is calculated for the local effect without considering the general effect of the drugs.

The following series of cases illustrates the result which may come from this inexact employment of the dangerous drugs known as local surgical anesthetics. This series of cases was reported to the Providence Society of Anesthetists, Feb. 28, 1913.

Number of cases	103
Minor surgical operations	35
Genito-urinary operations	68
Anesthetic	alypin, one of the safest of the cocain substitutes, in the strength of solution recommended. Amount of solution used unmeasured.
Death due to anesthetic	1
Serious difficulty	2
Satisfactory anesthesia	100

The cases of death and of serious difficulty are reported in detail. The numbers given to the cases here are not the serial numbers.

CASE 1 (June 15, 1912).—Patient, healthy man, aged 39. Operation, dilatation of stricture of urethra. Anesthetic, about 2 drams of a 10 per cent. solution of alypin, introduced through the meatus into the urethra and bladder.

About two minutes after the introduction of the anesthetic, the patient cried out and had a general muscular convulsion. During the next ten minutes there were about a half dozen such convulsions. Respiration ceased in seven or eight minutes. At the end of ten minutes the pulse had ceased to beat. Artificial respiration and stimulation were used, but in spite of these, the patient died.

CASE 2 (July 7, 1912).—Patient, healthy male. Operation, passing sounds for retention of urine. Anesthetic, unmeasured quantity of 10 per cent. solution of alypin introduced into urethra and bladder through meatus.

After about five minutes there was a general convulsion. The pulse became imperceptible. Respiration ceased. The patient was revived with difficulty after about two hours' work.

CASE 3 (Aug. 6, 1912).—Patient, apparently healthy male. Operation, dilatation of stricture of the urethra. Anesthetic, about 1½ drams of 10 per cent. solution of alypin introduced into urethra and bladder through meatus.

Anesthesia seemed very satisfactory. In three minutes patient became unconscious. After about five minutes there was a severe general convulsion. Respiration ceased. The pupils were widely dilated. The face was somewhat cyanotic. The pulse continued good. Treatment, artificial respiration and inhalations of oxygen. In ten minutes danger seemed to be passed. Patient recovered.

If an overdose of alypin was administered in these cases, it can be said that there is nothing in the literature of this anesthetic to indicate that the amount used was unreasonably large. The same criticism can be made of the dosage, as published, of nearly all the cocain substitutes. The revisers of the United States Pharmacopeia set the dose of cocain at ½ grain. The dose of all the cocain substitutes should be stated as clearly as this, putting in a subordinate position any statements as to strength of solution in which the proper amount of the drug may be employed. In this way further fatalities from these very valuable products may be avoided.

THE ELIMINATION OF GASTRIC DISTURBANCE PRODUCED BY SODIUM CARBONATE, IODIDS, OIL OF SANDALWOOD AND SIMILAR DRUGS

EDGAR G. BALLENGER, M.D.,
AND
OMAR F. ELDER, M.D.
ATLANTA, GA.

For a number of years we have been working to discover some method of obviating the gastric disturbance which is produced by remedies such as potassium iodid, oil of sandalwood, sodium salicylate, sodium carbonate, etc. This we have finally and satisfactorily accomplished. Remedies, such as oil of sandalwood, creosote and oleoresins administered in soft gelatin capsules may be prevented from disturbing the stomach by the process of hardening with formaldehyd the capsules in which they are placed.

Only slight hardening is necessary, especially if the capsules are kept for some time, as additional hardening comes with age. At first we immersed the filled capsules for one minute in a dilution of 1 part 40 per cent. formaldehyd solution to from 40 to 60 parts of water. The strength should vary with the ageing allowed.

From the time that the dilution mentioned is used two weeks should be allowed to intervene before administering the capsules. A more satisfactory method of preparing the capsules is to place them in open boxes in a closed vessel in which they are subjected to the vapor of the solution of liquor formaldehydi. About 15 c.c. of the solution should be used for each cubic foot of space in the closed vessel. The solution should be placed on cotton or gauze in a saucer or tray. The time required for hardening the capsules varies with the temperature and with the time that is to be allowed before they are administered. Six hours' exposure or less is enough for capsules which are not to be administered at once, while twelve hours may be necessary in preparing capsules for immediate use. These estimates are made for ordinary soft gelatin capsules at the ordinary room temperature, from 70 to 75 F. The capsules become hardened so that they are not digested by the gastric juice, but are digested by the intestinal secretion, if they have not been subjected too much to the vapor, in which case they may pass undigested. If dilatation of the stomach is present and the capsules or food do not pass into the intestines within the usual time, a greater degree of hardening of the capsules may be necessary. For the ordinary normal person capsules prepared as previously described will prevent gastric disturbance by carrying the medicament into the intestines before the capsules burst.

An even more satisfactory method of carrying through the stomach such remedies as sodium carbonate, potassium iodid, sodium salicylate, etc., is obtained by combining the desired remedy with mutton-suet and paraffin. When incorporated in such a mass the medicament is uniformly carried into the intestines without dissolving, as the stomach does not secrete a fat digestant. The suet is digested as it passes down the intestines and thus gradually the drug embodied in it is liberated. The paraffin is added to give additional hardness. The following combination is recommended:

		gm. or c.c.	
℞	Sodii carbonatis monohydrati	90	℥ iii
	vel		
	Potassii iodidi	90	℥ iii
	vel		
	Sodii salicylatis	90	℥ iii
	Sevi	30	℥ i
	Paraffini	16	ʒ iv

M. et fiat mass.

All the ingredients should be melted over water and while melted encapsulated in 00 gelatin capsules. The capsules may be filled with a fruit-spoon. The melted mixture should be of a creamy consistency, and the salt used should be previously powdered. The encapsulated product is a mass of the salt, the suet and the paraffin, is hard and remains unaffected by the gastric juice.

In the use of sodium carbonate, in the treatment of Bright's disease, as suggested by Martin H. Fischer, we have found this method of administration of decided value, as formerly it was quite difficult for the patient to take alkali in sufficient amounts to render the urine neutral or alkaline without producing gastric disturbance, with coated tongue and other symptoms.

The manner in which albuminuria and casts have disappeared under this treatment has been quite remarkable.

A number of patients who had been declined as risks by insurance companies because of albuminuria and casts have been passed by the insurance examiners after a few months of alkaline treatment. In order to secure the desired result we have added ¼ grain of phenolsulphonephthalein to each capsule of the monohydrated sodium carbonate preparation and have advised the patients to take from five to eight capsules daily as indicated to keep the urine light pink. This method constantly assists in regulating the amount of alkali to individual and varying requirements. The patients do not object to the use of the monohydrated sodium carbonate when so administered and can continue it over a prolonged period, when necessary. Potassium iodid so administered does not disturb the stomach, but produces its other physiologic and therapeutic effects.

In the use of remedies such as pancreatin, which it is desirable to liberate at once in the intestines and not to have dissolve slowly, ordinary gelatin capsules should be subjected to the formaldehyd vapor as suggested for the soft gelatin capsules. These capsules do not digest in the stomach and therefore carry the remedy they contain through without its being acted on by the gastric secretion. The remedies which we suggest to be incorporated in the suet and paraffin cannot well be given in ordinary gelatin capsules, as they may cause intestinal disturbance by liberating the entire amount of monohydrated sodium carbonate or potassium iodid at one point in the intestine instead of gradually freeing the mass as they pass down the tract.

We advise that in preparing the capsules controls of methylene blue and oil of sandalwood be used in test-capsules. If the capsules have been insufficiently hardened a glass of carbonated water taken two hours after the capsule has been administered will show by the eructation whether or not the capsule has broken in the stomach. If the capsules are subjected to formaldehyd vapor too long or if the gas be too strong the urine may be slow in becoming blue, or may remain unchanged. Capsules intended for immediate use may be subjected to considerably more formaldehyd than may be used on those which are to be kept for a few months.

MOVABLE SPLEEN

RUSSELL S. FOWLER, M.D.
Chief Surgeon, First Division, German Hospital; Surgeon, Methodist Episcopal (Seney) Hospital
BROOKLYN

The term "movable spleen" includes all cases of mobility of the spleen, while the term "floating spleen" is restricted to those cases of movable spleen which are congenital in origin, in which there is a long mesentery allowing of excursions of the organ to any part of the abdominal cavity. The latter condition is comparable to floating kidney in which the mesonephron is so developed as to make the kidney an intra-abdominal organ.

During the past few years I have noted the mobility of the spleen in many laparotomies not involving septic processes. From these observations it can be stated that the normal spleen is but slightly movable, its normal excursion not exceeding 1½ inches; in fact, it is held rather rigidly suspended.

Abnormal mobility may be (*a*) congenital, owing to the development of a long mesentery; or (*b*) acquired, owing to elongation of the normal mesentery and suspensory folds, (1) from strain with or without relaxation of the abdominal walls (in the former event repeated confinements play the same rôle as in movable kidney); or (2) from tractions on the mesentery by increase in the weight of the organ (hyperplasias, cysts, tumors). Increase in size, however, does not necessarily mean marked increase in mobility.

Excessive mobility of the unenlarged spleen is rare. In a continuous hospital service totaling over thirty years, I have seen but one case. In enlarged spleen mobility is common, but even in these cases excessive mobility is not often seen.

Torsion of the pedicle is followed by atrophy of the splenic tissue in some cases and gangrene in others.

Movable spleen often does not present any difficulty in the diagnosis. Nevertheless, owing to the rarity of the affection, many errors are made. The spleen may be found in any part of the abdomen and may or may not become adherent. Unless it becomes adherent, twisting of the pedicle is common. The mass may be mistaken for a tumor of the ovary or pancreas, but is more commonly mistaken for a left movable kidney. The discovery of the characteristic notch makes the diagnosis certain. In some cases cystoscopic examination may be necessary in order to differentiate the tumor from the kidney. There are no blood changes unless the case is complicated by malaria, unless torsion has occurred in a splenomegaly, or unless acute torsion of the pedicle exists.

Many methods have been devised for holding a movable spleen in position. Tuffier, Kouwer, Rydygier and Bardenheuer have devised methods. The consistency of the spleen does not lend itself to suture. Operations which place the spleen outside the peritoneum by suspending it in a sort of pocket are best if splenopexy is undertaken at all. The results of the operation of splenopexy, however, are not such as to encourage its continuance. These patients suffer more or less from dragging pain. Splenectomy is more advisable.

In movable spleen, the excision of the organ produces slight, if any, change in the blood-picture. In splenic anemia the leukocytes rise to normal and after some months the red cells become normal.

The prognosis is good. Relief of symptoms is immediate.

The mortality of splenectomy for movable spleen is slight. Bland Sutton[1] reports that in twenty cases in which splenectomy was done previous to 1897 there were no deaths.

Schwartz[2] reports ten cases of extirpation of floating spleen; eight patients recovered. One patient died two months later of cachexia existing at the time of operation, the other of peritonitis. There was torsion of the pedicle in six cases. In all of these cases the spleen was enlarged from malaria. In only one case did the malaria recur.

Webster[3] reports a case of enlarged spleen adherent in the right iliac fossa. The pedicle had two or three twists. The patient, a woman, had noticed a swelling in the right iliac region seventeen years before. Thirteen years later the abdomen had been opened but the operator mistook the enlarged spleen for a tumor of the right kidney and desisted from further intervention. This was a case of wandering spleen with attacks of pain from twisting of the pedicle. The spleen was somewhat enlarged and congested, and contained considerable fibrous tissue.

[3] Webster, J. Clarence: A Case of Successful Removal of an Enlarged Spleen, The Journal A. M. A., April 4, 1903, p. 887.

Stierlin's statistics published in 1847, based on thirty-two cases of splenectomy in floating spleen alone, collected from the literature, shows a mortality of 6.25 per cent. Some of these cases were malarial. Bossel-Hagen's[4] statistics show twenty-six cases of floating spleen complicated by malaria, with one death. In a total of forty-three cases of floating spleen, some malarial, some not, reported previous to 1905, forty patients were cured. The three deaths were due to faulty technic.

The history in the present case, in which the patient was referred by Dr. Calogero Giovinco, is as follows:

REPORT OF CASE

An Italian woman, aged 25, the mother of several children, after her last confinement began to have pain in the right half of the abdomen. This pain was dragging in character and at times quite acute and agonizing. A few months later she noticed a swelling in the left iliac region. Vaginal examination disclosed a large mass in the pelvis which was not connected with the uterus, ovaries or tubes. By manipulation it was possible to place this mass in any part of the abdominal cavity. It was about the size of a large kidney and seemed to find its resting place most readily in the right kidney region. The examination was not easy as the patient complained of considerable pain. Examination of the kidney region disclosed a loose right kidney. The left kidney seemed normal. On again feeling for the mass it could not be found and the natural conclusion was drawn that it was the kidney that was at fault. Suspension of the right kidney was performed at the German Hospital. Before placing the suspension sutures an attempt was made to make the kidney descend into the pelvis, in which the original mass had been felt, but it was impossible to cause it to descend into the lesser pelvis. This aroused suspicion as to the nature of the tumor originally noted, so after the completion of the kidney operation the abdomen was opened and the tumor found to be a movable spleen which could be moved to any part of the abdomen. Fixation was not practical, so the pedicle, about 1½ inches thick, was ligated in three sections and the spleen removed. A fourth ligature was placed on the pedicle as a precautionary measure and the raw surface of the pedicle covered.

The after-course was uneventful. The blood-count made a few hours after the operation showed 3,900,000 red blood-cells and 34,200 white blood-cells. Daily blood-counts thereafter for twenty-seven days showed a gradual decrease in the red cell-count for a few days and then a gradual increase until on the twenty-seventh day the count was 4,147,000. There was a gradual decrease in the number of white cells for the same period; on the twenty-seventh day the white count was 12,880. A few normoblasts were seen from the eleventh to the twenty-first days.

301 DeKalb Avenue.

Care of Cows in a Certified Milk Dairy.—The production of certified milk with a minimum bacterial count requires almost as much care as the preparation for an aseptic surgical operation. A certified milk dairy near Chicago has the following routine in the preparation of the cows and the stables before milking: (1) Cows enter barn through curtained door to prevent entrance of flies; (2) barn is swept and washed out; (3) cows are cleaned: (*a*) first man brushes and currycombs the whole cow; (*b*) next man scrubs the hind quarters with a brush, and moistens tail; (*c*) third man washes the udder and hind quarters carefully with warm water; (*d*) last man dries each udder with an individual sterile towel; (4) barn is again washed out; (5) spraying machine is drawn through the barn, covering ceiling, cows and floors with a fine, antiseptic mist spray, settling all dust and inhibiting bacterial growth. Milking now commences.

A SOURCE OF DEFENSE TO HETEROPLASTIC TISSUE GRAFTING *

JAMES B. MURPHY, M.D.
NEW YORK

A year ago I reported some experiments dealing with the growth of tissues of foreign species in the chick embryo.[1] It is a well-known fact that it has been found impossible to graft the cells of one animal into an adult of another species. I have shown, however, that the embryo not only lacks entirely the quality which would make it an unsuitable host for the tissues of another species, but also offers conditions even more suitable for their growth than do the adults of the original species from which the tissue was derived. What is responsible for this difference between the adult and the embryo? Lambert and Hanes[2] have shown that the plasma of one species is an excellent medium for the growth *in vitro* of the cells of another, which indicates that the difference is not a simple matter of suitability of nutriment. If the difference depends on a defensive mechanism, the result of the action of a single organ or a special tissue, we should be able to supply this lacking quality by grafting bits of adult organs into the embryo. Under the influence of this idea the following experiments were undertaken.

Chick embryos were inoculated simultaneously with a fragment of a rapidly growing rat sarcoma and a bit of some adult chicken tissue. Both of the implantations were made in the outer membrane, but in different locations. The results have been clear-cut and striking. The various organs and tissues, with two exceptions, have no effect on the growth of the graft of foreign tissue. The kidney, which grows as well as either spleen or bone-marrow, can be grafted side by side with the rat sarcoma and the two intermingle freely without producing any retarding effects on the growth of the rat tissue. A remarkable difference, however, was observed when the chick embryo was provided with a bit of adult chicken spleen. In this case the embryo exhibited a degree of resistance to the growth of the foreign tissue which was as great as that of the adult chicken. Furthermore, it was found that if the rat sarcoma is allowed to become established and to grow actively in the embryo for three or four days, at which period the graft of adult chicken spleen is introduced on the opposite side of the egg to the sarcoma, the latter undergoes a rapid retrogression. Indeed, this process is so rapid in some cases that it progresses to complete absorption within eight or nine days of the introduction of the spleen. The adult bone-marrow was ascertained also to exert a retarding influence on the sarcomatous tissue graft in the embryo, but its action is less marked than that of the spleen.

Whatever the various functions of the spleen may be, these experiments show conclusively that when that organ in the adult state is supplied, the embryo chick otherwise subject to heterotransplantation becomes as resistant as the adult animal to growth of alien tissues. Hence the spleen and, to a less extent, the bone-marrow provide a defensive mechanism that prevents the development of foreign tissues in the chick embryo.

THE HOUSE-FLY AND DIARRHEAL DISEASE AMONG CHILDREN

DONALD B. ARMSTRONG, M.A., M.S., M.D.
Superintendent, Bureau of Public Health and Hygiene, Department of Social Welfare, New York Association for Improving the Condition of the Poor
NEW YORK

The question concerning the relationship of the house-fly to disease is one about which much is said, and at the same time concerning which very little has actually been determined. It is only in a few Southern communities, such as Jacksonville, Fla., Richmond, Va., and Asheville, N. C., that accurate scientific field studies have been made into the problem of disease carriage by these insects. The popular campaign against the house-fly, on the other hand, is almost universal and is just as extensive in the North as in the South, although the few facts known concerning fly transmission were determined under and are largely applicable to Southern conditions. The present study is probably the first definite attempt in this direction in a Northern community.

In this work attention was paid to all forms of morbidity and mortality, but special emphasis was laid on obtaining accurate statistics concerning that group of disturbances with which it is most logical to associate the fly in Northern communities, namely, diarrheal diseases of infants. The results seem to indicate that the fly is a much-neglected factor in the etiology and transmission of summer diarrhea. Greater attention should be given to the elimination of the insect by all those interested in the prevention of infant mortality, and by all, including infant-welfare workers, nurses and physicians, who are in a position to educate the mothers in the necessity of protecting their infants from the ever-present disease carrier.

The work on which this conclusion was based was carried on during the past summer (1913) in the borough of the Bronx, New York City, in a neighborhood inhabited solely by Italians, and presenting the typical conditions associated with overcrowding, filthy streets, refuse-littered vacant lots, waste-strewn roadways, insanitary stables, etc. One area, inhabited by 311 families or 1,725 individuals, and containing a population of 362 children under the age of 5, was selected, and within this area every effort was made to eliminate the house-fly and to break the contact which the insect was supposed to make between filth and food. Another area containing the same number of families, was permitted to pursue its usual insanitary course. Through nurses, supplied by the Bureau of Public Health and Hygiene and by the New York Health Department, careful records of all the facts of morbidity and mortality in the two areas were taken weekly for a period of eight weeks from July 21 to September 13. These findings were later compared and it is on the most *significant* of them—namely, those dealing with diarrheal diseases of infants — that the greatest emphasis should be placed.

The methods of opposing the activity of the house-fly may be briefly outlined. First, an educational campaign was carried on by nurses among the mothers in the first area selected. The oral injunctions of the nurses were supplemented by the distribution at frequent intervals of literature in Italian and English, describing and depicting house-fly dangers. Free tickets were distributed in the block admitting the people to a moving-picture theater near by, where an arrangement was made by which there was displayed for a week the anti-fly picture film. The seventeen hundred doors and windows in the area were carefully screened. Under the auspices of the local Boy Scout organization, large fly-traps were constructed and placed in the courtways, yards and stables.

In so small a number of children the mortality figures will be too few to be of any significance. On the other hand, the results of the work from the standpoint of diarrheal morbidity are striking and significant. It was found, for instance, that there were in the protected area twenty cases of severe diarrheal disturbances in infants under 5 years of age, while among the "outside" infants, in the same age-group, there were fifty-seven similar cases. The ratio here is nearly 1 to 3. It was found further that for the protected area the total days of sickness of diarrheal disease among infants was 273 days, giving an average case duration of 13¾ days. while among the children of the "outside" families the total number of days of sickness was 984, with an average case duration of 16⅓ days, indicating that not only was there more sickness of this character in the uncleaned area, but the lessened resistance of the infants is reflected in the greater severity and protractedness of the cases.

The two areas selected for comparison were decided on originally because they were comparable in practically every particular. Not only was the population the same in number and character, but also the amount of infant-welfare work, limited to the activities of one diet-kitchen, was found to be uniform throughout the two sections. An analysis was made from time to time of other agencies known to be influential in infant welfare, such as methods of feeding, type of milk used, etc. It was found, for instance in one of the studies that of the infants in the protected area 88 were breast-fed and 14 bottle-fed, while among the infants "outside" 85 were breast-fed and 15 bottle-fed—not a sufficient difference to justify the consideration of it as of any marked importance in the morbidity differences. While these separate investigations were carried on, every effort was made to prevent them from being educational campaigns. In so far as it was possible, it was hoped that the differences in morbidity and mortality, should there be any, could, with justice, be accredited to the anti-fly campaign.

While it is believed that the elimination of flies had a great deal to do with the reduction of diarrheal disease among children, there is no doubt that the general sanitary improvement had a decidedly beneficial influence on the general physical welfare of all the people in the district. In the protected area there were 110 cases of sickness recorded; among the "outside" families there was a total of 165 cases. The ratio between the protected area and the unprotected one as regards non-communicable disease was 36 to 40. This leaves a ratio of 74 to 125 in the matter of communicable disease reported for the two districts.

The latter figures, as well as those dealing with diarrheal disease, are subject to the just criticism of having been derived from a small number of people, and from an experiment conducted for only a short period of time. They are, of course, not conclusive evidence, but they are worthy of serious consideration by all those interested in infant welfare. Practical results of the investigation indicate the possibility of immensely improving the sanitary condition of a community by the simple procedure of enforcing those sanitary regulations which have to do with fly-breeding nuisances. The work is of importance because of the direction it should give to further investigations along this line in

Northern cities. The statistical results justify the placing of a greater emphasis on educational work among mothers regarding the dangers of the house-fly in the lives of the infants. This element should become a more important factor in infant-welfare work. It is probable that a similar study on a larger, more comprehensive plan, and covering a longer period of time, will be conducted another summer under the auspices of the Bureau of Public Health and Hygiene of New York City. Until the present results are affirmed or revised by further research, the physicians and public-health workers throughout the country should appraise the facts already ascertained at their full value and utilize this seemingly important factor in the universal effort to improve the welfare of society's potential citizen.

THE EFFECTS OF NITROGLYCERIN ON THOSE ENGAGED IN ITS MANUFACTURE [*]

GEORGE E. EBRIGHT, M.D.
SAN FRANCISCO

An examination of the literature for the past twelve years revealed very little regarding the state of health of those who habitually come in contact with nitroglycerin or nitroglycerin products. Through the courtesy of the Dupont Powder Company, I was enabled to make investigations in the company's factory at Hercules, California, and to examine some twenty men employed there.

It is fitting first to consider the physiologic action of the nitrites. They are essentially cardiac depressants. They cause vascular dilatation by paralyzing the vagus centers and the centers for vascular tone. They cause tumultuous action of the heart by relaxing inhibition, lower respiratory action by paralyzing the respiratory muscles and impair the oxygen-carrying power of the blood by converting oxyhemoglobin into methemoglobin. They cause a sensation of heat, a lowering of body temperature, throbbing pain in the head, beating carotids, quickening pulse, flushed face and vertigo. Sugar may be caused to appear in the urine, urination is increased and large quantities of low-gravity urine may be passed.

Laws,[1] in an article on "Nitroglycerin Head," finds that the increased action of the heart is followed by retardation; that the headache may be preceded by complete loss of vision; that nervous manifestations of acute poisoning are sometimes so severe as to amount to acute mania. In a private communication he refers to a man, who, on becoming poisoned, would first complain of a severe headache, then become wild and incoherent, and finally run about shrieking and hitting his head against trees, walls or any other object. It was necessary to restrain him until the attack was over. He tried to establish an immunity to nitroglycerin poisoning by perseverance, but after several trials gave up the attempt. Another patient, a mild-mannered fellow, would become violent, striking at any person or object within reach. Laws further observes that all those who work in nitroglycerin are sooner or later troubled with tachycardia on exertion, and that nitroglycerin is a marked aphrodisiac, most nitroglycerin men having large families.

Observation of the working conditions in the factory at Hercules led me to the following conclusions: Occasionally, among the men who work in the nitroglycerin factory, one will be found who is immune to the ill effects of the drug, but this is so much an exception to the rule that it is safe to say that all persons working in nitroglycerin powder works are acquainted with the very disagreeable experience of the peculiar headaches which characterize acute nitroglycerin poisoning. The degree of exposure to nitroglycerin necessary to produce the headaches varies with the individual, the weather, and the state of immunity. A new man is very susceptible, and warm weather greatly enhances the incidence and severity of the symptoms. After one has worked for three or four days, a comparatively high degree of immunity is established, which persists so long as he remains at his work; nevertheless, should he be exposed to unusually large doses, headaches are likely to occur. This immunity, on the other hand, is rapidly lost, and even after the absence of a couple of days the man, on returning to the works, will experience the usual toxic symptoms. It is a common practice among nitroglycerin workers to place some of the product on their hatbands during periods of absence from the factory, in order to maintain their immunity.

The exposure necessary to produce headaches varies from merely shaking hands with men who have been handling it, to handling of or exposure to large quantities.

A throbbing headache is characteristic. It frequently begins in the forehead and moves to the occipital region, where it remains for from an hour or two to three or four days. It may be associated with a sense of exhilaration at first, but most of the patients are depressed. Restlessness and inability to lie quietly in bed are often present. Many patients cannot sleep, so that the unfortunate victim is doomed to make the best of his pain propped up in bed through a couple of sleepless, restless nights, often with nausea or vomiting, and in severe instances with diarrhea. Maniacal attacks were not called to my attention by the men I examined.

Concerning permanent effects, the general health of the men working in nitroglycerin appeared to be in no way impaired; on the other hand, they were in remarkably good condition. Several factors bore on this result. In the first place, they were selected men chosen for reliability and sobriety, and a bonus system was in vogue for continued good service. On account of the hazard of their occupation, smoking tobacco was not used. With the exception of one case of chronic valvulitis of rheumatic origin, the examination of their hearts showed no abnormalities. The examination of the radial arteries showed no abnormal changes. Blood-pressure ranged within normal limits. There was no evidence of chronic low blood-pressure, and no appreciable relaxation of the arteries or of the capillaries. I found no instances of shortness of breath, nor did Dr. Fernandez, who has charge of the health of the men, notice that it ever occurred. As far as the complexion of the men was concerned, there were no evidences of destructive blood-changes, such as might have been anticipated by constant destruction of oxyhemoglobin. The amount in the system at any one time was too small.

Examination of the urine of nine men revealed no glycosuria. This included one man suffering from nitroglycerin headache. In his case there was no flushing of the skin or relaxation of the radial artery, although he was experiencing throbbing pain in the head, and dizziness and nausea. His systolic blood-pressure was 122 mm. Hg.

---

[*] Read before the California State Medical Society, Oakland, Cal., April 16, 1913.

[1] Laws, C. E.: Nitroglycerin Head, The Journal A. M. A., March 5, 1910, p. 793.

Alcohol enhances the toxic symptoms by relaxing the blood-vessels. This is true to the degree that a man who has been exposed to nitroglycerin all day without ill effects may precipitate a severe headache in a very few minutes by taking a cocktail.

As may be readily imagined, the men working in a well-organized factory are protected from certain dangers that may obtain where the personal habits of those employed in the handling of nitroglycerin are not strictly governed. For instance, in the mines of California, where considerable blasting is done, it is generally recognized that so-called powder men are inclined to be irritable and pugnacious, and that it is unsafe to pick a quarrel with them.[2] The explanation of this probably lies in the fact that the toxic action of nitroglycerin is enhanced by the action of alcoholic beverages which are indulged in extensively in mining towns. A case in point came to my notice. A construction foreman, a man employed on account of his expertness in the use of high explosives, was engaged in excavating for the foundations of a bridge. On a certain day this man handled between a ton and a ton and a half of dynamite. He arrived at his lodgings in the evening with a splitting headache. Being advised that whisky would be beneficial for his headache, he indulged freely in that remedy, and within two or three hours had developed an acute mania with homicidal impulses. Before being restrained, he began shooting with a revolver right and left, wounding one of his own friends and killing a bystander.

An interesting description of cordite eating that occurred in the British Army during the Boer War is described by Lieutenant-colonel R. J. S. Simpson, C.M.G., as follows:

> Such a trifling matter as a dearth of matches led to a knowledge of the drug; for the men extracted the cords from the Lee-Metford cartridges to light their pipes and cigarettes with, and found that it affected their heads. Thus it may be supposed the fatal knowledge would arise and spread. The craving for drink, which could not be had on the field, would conduce to the use of the narcotic once it became known. The drug is taken in two or three ways, e.g., eaten solid, boiled down in water or tea, or mixed with beer. In small doses to those not accustomed to its use, or to other narcotics, cordite, like some other drugs, has a by no means pleasant effect, as Major Jennings found to his cost on eating a quarter-stick, by way of experiment. The stuff was sweet in the mouth, but it gave him a "most racking, splitting headache." The habitué is able to take the contents of a cartridge or more. His face flushes, his head throbs and seems to swell, and then in about fifteen minutes comes long sleep. On awakening he has an intense headache, thirst, etc. Taken with beer or hot tea the first effects are wild delirious intoxication, and this is followed by sleep. Morphin, opium and alcohol in small quantities are "pick-me-ups" after cordite, and apparently some men have used cordite as a reviver after alcohol. Optical and mental delusions, timidity, weakness and general breakdown, moral and physical, result from prolonged use of cordite as a drug.

Apropos of the cordite habit, it might be thought that workers in a nitroglycerin factory could possibly become addicted to a nitroglycerin habit. It is only necessary to breathe the atmosphere of a powder factory for a little while to realize that the dread which the workmen have of nitroglycerin headaches precludes any likelihood of the acquiring of a pernicious habit.

On account of the small series of cases taken, a positive statement concerning chronic changes in the cardiovascular system is not permissible, but as far as my observations go, it may be said that no permanent ill effects could be demonstrated. As healthy as any man observed were two, one of whom had been employed eighteen years and the other twenty.

Of acute poisoning, it may be said that in most instances the work of the men is not interrupted, although it may be for a day or two, after which the comparative immunity is established.

209 Post Street.

A CASE OF OXYCEPHALY

IRVING F. STEIN, B.S., M.D.
CHICAGO

This condition, which is also described as *Thurmschädel, Spitzkopf,* acrocephaly, steeple-head, turritum caput or tower-head, and *tête à la Thersite* has received but little attention in the literature. Most of the cases reported, according to Fletcher,[1] who reviewed the literature in 1910, were considered chiefly because of the curious cranial deformity. Fletcher found only between eighty and ninety cases, and since then a few more have been reported by Brav,[2] Almond[3] and von Schevensteen.[4] This condition is probably more common than statistics would have us believe, only the severe cases—those in which there is early and rapid blindness—being usually reported, and those first coming under the notice of the ophthalmologist.

This case is typical of the mild form in which the sight is but little interfered with.

REPORT OF CASE

History.—Miss E. R., aged 19, a Roumanian Jewess who had done office work, entered the medical ward on the service of Dr. Arthur R. Edwards in November, 1912, complaining of palpitation, shortness of breath, dry cough and severe headaches. Patient stated that she had had some precordial distress as long as she could remember, but that the symptoms had not been severe enough to keep her in bed until the past few weeks. Palpitation and shortness of breath were marked on slightest exertion, being caused even by turning in bed. Precordial pain and dizziness were often present also. The cough, which had been present for four or five weeks, had never been productive of sputum, but had caused the patient to vomit occasionally. There had been no hemoptysis. The appetite was poor and bowels slightly constipated. There was no gastric distress. Headaches had always been troublesome, but more severe in the past weeks, being usually on the left side of the head and behind the eyes, and of a throbbing nature. The eyes had always been large, and the patient did not believe they were becoming more prominent. Patient had been wearing glasses for astigmatism, and there had been no appreciable difference in vision in the past few years. Weakness was very marked and often came in spells; the patient was also subject to spontaneous crying spells and nervous fits. There were no night sweats, no fever, and no urinary or menstrual complaint. The patient had been subject to frequent attacks of tonsillitis, but had never had scarlet fever, rheumatism or chorea. She was a patient in the Michael Reese Hospital in 1908 with heart disease and nervous fits which were called hysteria. The father was a patient in the Michael Reese Hospital in September, 1912, when he gave a history of lues, but Wassermann tests made on both his blood and cerebrospinal fluid were negative. The mother died of tuberculosis. There were no brothers or sisters.

---

[1] Fletcher, H. Morley: Quart. Jour. Med., 1910-1911, iv, 435; abstr., The Journal A. M. A., June 3, p. 1688.

[2] Brav: Ann. Ophth., 1912, xxi, 1.

[3] Almond: Alienist and Neurol., 1910, xxxi, 487.

[4] Von Schevensteen: Ann. Soc. de méd. d'Anvers, 1911, lxxiii, 102

Physical Examination.—The general appearance was that of a dark-complexioned young (white) woman with black curly hair and large bulging eyes, lying quietly in bed in no apparent urgent distress. Hair and scalp were negative. The cranium was long in the vertical, and narrow in the anteroposterior and transverse diameters, with a prominence at the bregma. The ears were negative. The nose, except for a slight deviation to the right, was negative. The eyes were very large and prominent. The palpebral fissure was wide. There was no von Graefe sign. The pupils were equal and regular and reacted to light and in accommodation. There was no nystagmus, but a slight external divergent squint with some limitation of motion of the eyeball to the left. Sclerae and conjunctivae were clear. The teeth were in good condition, the tongue clean and moist. The hard palate was narrow and highly arched. The pharynx was negative. The neck was negative as regards adenopathy, goiter or abnormal pulsations. The chest was symmetrical and expansion was equal on inspiration. Breasts were well developed, equal in size, and contained no masses. The lungs were negative except for a slight impairment of resonance with increased tactile fremitus in the left apex. There were no râles or rubs.

Heart: The apex impulse was visible in the fifth left costal interspace just outside of the nipple line. The heartbeat was palpable as a short, sharp snap at the apex and a distinct throb at the pulmonic area. To percussion the heart dulness extended from the third left interspace above, 3 cm. to the right and 12 cm. to the left of the midsternal line. On auscultation a distinct presystolic murmur was heard leading up to a loud, sharp first tone at the apex, and over the pulmonic area the second tone was markedly accentuated.

Examination of the abdomen, extremities and genitalia was entirely negative.

The blood examination on admission gave: hemoglobin, 72 per cent. (Sahli); red blood-cells, 4,000,000; white blood-cells, 7,400; differential count: 83 neutrophils, 12 small mononuclears, 3 large mononuclears, 1 eosinophil and 1 basophil by the skeleton stain; blood-pressure, right 115, left 110. Wassermann reaction was negative.

Urine examination was negative for albumin, casts and blood. The urine was acid, specific gravity 1.023.

The eye-grounds were examined by Dr. Mortimer Frank, after dilatation of the pupils with homatropin, and the fundi reported negative.

The roentgenogram showed the typical dimpling of the inner table of the skull which Fletcher and others have described as characteristic of oxycephaly and hydrocephalus.

The cardiac complaint—a pure mitral stenosis—brought the patient to the hospital, and is in no way connected with the condition reported.

There was a marked resemblance to the other cases reported. The shape of the head, prominence and size of the eyes, slightly deviated nose, high arched palate, intense headaches, "nervous fits" (which were previously ascribed to hysteria by former medical attendants) and characteristic dimpling of the inner table of the skull, as shown in the ronetgenogram, establish the diagnosis of oxycephaly in this case. In this, as in other reported cases, the intelligence is not impaired.

Michael Reese Hospital.

Effective Functioning of Health Departments.—The safeguarding of the public health is the function of health departments. As we equip these departments with men and means to carry on the work, so do we make community health more assured and life more secure.—*Bull. Chicago School of Sanitary Instruction.*

STRANGULATED FEMORAL HERNIA IN A PATIENT AGED 83

Walter W. Mott, A.B., M.D., White Plains, N. Y.

The case I shall report is of interest because of the few successful cases recorded of resection of the intestine for acute surgical conditions in patients of advanced age. In two cases, one reported by Fiolle[1] of Marseilles and one by Howitt[2] of Guelph, Ontario, the patients, each aged 81, have been the oldest noted in the literature for the past ten years.

History.—The patient, a woman, aged 83, referred by Dr. E. Clark Tracy, had previously enjoyed good health. She had had a reducible inguinal hernia on the left side for some years, but had never noticed any swelling in the right groin. Thirty-six hours before the operation, she began to have cramp-like pains in the abdomen, not localized, and recurring in paroxysms. Vomiting occurred with the onset of the pain, and continued at intervals until the operation. The vomitus was a thin, bile-stained watery mucus, and at no time fecal. There was no abdominal rigidity and no evidence of hernial protrusion. An enema was given and returned with fecal matter and flatus. The pain and vomiting were attributed to an indiscretion in diet, in the absence of any physical signs. Finally, on October 11, about thirty-two hours after the onset of symptoms, a small pear-shaped mass was made out in the right femoral region. This proved to be a hernia arising from beneath Poupart's ligament and passing forward and upward. Gentle taxis was tried for ten minutes, but proved unavailing. The patient's general condition was fair, although somewhat weakened from vomiting, and immediate operative interference was decided on. She was accordingly removed to the White Plains Hospital and prepared for operation, a dry shave and iodin being used. Morphin sulphate, ¼ grain, had been given during the preceding twelve hours, and the patient was still partly under its influence.

Operation.—Under local anesthesia (cocain 1:500) a vertical incision was made over the hernial mass, the upper end of the incision extending one-half inch above the lower border of Poupart's ligament and curving slightly outward. A thin-walled loculated sac was found and easily isolated. On opening the sac a small quantity of odorless bloody fluid escaped. The sac was found to contain a mass of omentum the size of a plum, and a loop of ileum about 3 inches long. The intestine was purplish with glistening peritoneal surface. The strangulated omentum was ligated and resected and the femoral ring enlarged enough to permit the pulling down of a larger loop of intestine to relieve the impeded circulation. The intestine at the site of the constriction appeared black and lusterless. No pulse could be felt in the mesenteric vessels supplying the strangulated loop. Hot compresses were applied to the injured intestine and renewed for twenty minutes, in the hope of restoring vitality. At the end of this time the color of most of the loop had improved, but the site of constriction still appeared sphacelous and it was decided to resect. Until this point the patient had had no general anesthetic, but the dragging on the mesentery was causing considerable pain, and light ether anesthesia was begun and continued to the end of the operation. Clamps were applied to healthy gut on either side of the strangulated loop, and a piece of ileum 6 inches long was resected. An end to end anastomosis with sutures was then made, and the united intestine replaced, with some little difficulty, through the femoral ring into the abdominal cavity. Two chromic sutures were placed between the lower border of Poupart's ligament and the pectineal fascia, the neck of the sac being included in these stitches, as it was very friable and not large enough to afford tissue for tying off separately. Several interrupted plain gut sutures were placed in the cribriform and subcutaneous fasciae, and the skin closed without drainage. The patient left the table in fair condition.

2. Howitt: In the discussion of a paper by J. Y. Brown, Primary Bowel Resection vs. Artificial Anus in the Treatment of Strangulated Hernia, with report of 7 cases, Am. Jour. Obst., November, 1905, No. 2, p. 754.

Post-Operative History.—Colon irrigations were started at once, and nutrient enemas were given, while feedings of water, albumin-water and whey were being slowly increased. Abdominal distention was considerable for several days, and the patient vomited twice, but nothing fecal. The distention was finally overcome by repeated enemas and stupes, together with the colon irrigations. The bowels moved spontaneously on the tenth day and convalescence was uneventful. A small amount of colon bacillus pus was evacuated from the upper angle of the wound, which thereupon healed kindly throughout. The patient was taken out of bed as soon as possible to avoid pulmonary hypostasis and was discharged from the hospital on the twentieth day after the operation. Since then she has been on regular diet, and has a normal bowel movement each day, the latter being assisted by the occasional administration of liquid petrolatum, ½ ounce. There is no abdominal distention and the femoral ring remains firmly closed.

CLINICAL REPORT OF A CASE OF RABIES TREATED WITH NEOSALVARSAN AND QUININ

TOGETHER WITH A CASE OF LYSSOPHOBIA

Miley B. Wesson, B.S., M.D., El Paso, Tex.

The interest aroused by the publications of Tonin,[1] Moon[2] and Harris[3] in the finding of a drug that would act as a specific for rabies warrants the publication of a report of this case, which was treated with both neosalvarsan and quinin.

C. M., Mexican, aged 10, was bitten, July 18, 1913, by a rabid dog, the left forearm and throat being badly lacerated; the wounds were cauterized and dressed daily at the charity clinic. Pasteur treatment was persistently urged but refused. About August 2 the boy became depressed and anxious and told the office girl at the clinic that he knew he was going mad. There were cephalalgia, loss of appetite accompanied by gastric uneasiness and nausea; the patient's mental condition gradually grew worse and at times he was intermittently delirious. I saw him on the morning of August 6; the wounds were healed, but the scars appeared abnormally livid. The patient was restless, breathing was rasping and was frequently interrupted by pharyngeal and respiratory spasms; there was a slight dysphagia. A general hyperesthesia was present with photophobia and intolerance to sound. The eyes reacted to light and accommodation; tendon and skin reflexes were slightly exaggerated; the grip of the left hand was much weaker than that of the right, and when the boy attempted to walk the left leg had a tendency to give way, so that he required support on that side.

I wrapped him in a blanket and carried him to the hospital in an open car (before permission for hospital treatment could be revoked by the family). The jolting of the car, the noises and the sunlight did not seem to bother him—in fact, the novelty of an automobile ride appeared to arouse him. As soon as he reached the hospital, however, he returned to his former lethargic condition.

Following the method of Tonin (who in July, 1912, reported a "hopeless" case of rabies in a 13-year-old child cured following the use of 0.3 gm. of salvarsan, potassium iodid, tepid baths and stimulants) *this patient on admission to the hospital* was given 0.4 gm. neosalvarsan (intravenously), repeated in twenty-four hours. On this day, Moon's report of rabies cured in dogs with quinin by mouth was received. So the patient was given quinin sulphate by mouth (106 grains per day, divided into three doses), and this was continued up to within a few hours of the end. During the course of his illness the temperature ranged from 100.2 to 106.2 F., and pulse from 138 to 170.

Forty hours before death he was unable to swallow egg-nog or other thick liquids, but he could swallow water up to within four hours of his death, though with great difficulty, suffocating pharyngeal spasms occurring after a few swallows. The patient never became violent. Paralysis became general and death took place on the second day, from asphyxia during a slight paroxysm.

In this case neosalvarsan, quinin and other drugs had no influence in checking the advance of the disease or modifying its course in any way, other than possibly controlling convulsions; but if either neosalvarsan or quinin have this property possessed by none of the sedatives, then they are invaluable in the treatment of rabies.

CASE OF LYSSOPHOBIA

Frequently cases of hysteria are diagnosed as hydrophobia, and when recovery occurs the cure is erroneously attributed to the last drug used. The following case is typical:

G. J. B., an Arizona mine-owner, was bitten on the right little finger, Nov. 11, 1913, while asleep, by a "hydrophobia skunk" (a small striped variety of skunk supposed by the cowboys to be always infected with rabies). He developed a pseudohydrophobia on the second day (though he had never seen a case of rabies) and paroxysms were so violent that he had to be restrained by his physician during the two days' trip to El Paso. I saw him Nov. 16, 1913; he was anxious, haggard looking and his eyes fairly blazed; there was difficulty in breathing and dysphagia was so marked that he had been practically without food or drink for two days; he was having frequent convulsions and appeared to have partially lost the use of his limbs. Severe pains radiated from the bitten finger to the back of his head.

Examination, made on admission to hospital, showed that there was no paralysis, the superficial and deep reflexes were normal, and paroxysms, though violent, did not simulate those of rabies. The temperature was 97 F. and the pulse 108. The patient was started on the Pasteur treatment, Negri bodies having been found in the skunk's brain. The convulsions were controlled by morphin, so suggestion instead of quinin or neosalvarsan was used and all symptoms disappeared. The patient was able to leave the hospital on the third day.

A UNIQUE CASE OF BOWEL OBSTRUCTION

W. D. Hamaker, M.D., Meadville, Pa.

History.—Mrs. P., aged 72, a patient of Dr. Best, has had fair health for many years with the exception of obstinate constipation. Nov. 1, 1913, she was seized with severe abdominal pain and nausea. Later on she had considerable distention and great tenderness over the abdomen. The tenderness was general and there was no resistance or tumefaction at any point. November 2 decided symptoms of obstruction showed themselves. High enemas given that day failed to produce much result, except one fairly large stool with some gas. Large doses of calomel and other cathartics had been given previously. Finally fecal vomiting appeared with hiccoughing.

Operation.—November 3 a laparotomy was performed. As the urine was almost entirely suppressed, November 2 and the morning of November 3, chloroform and oxygen were used. A median incision was made and the first thing noticed was a marked distention and congestion of the small intestine. When the hand was passed in, deep in the cavity was found a mass, which, when drawn up, showed a black spot at one end. The mass proved to be Meckel's diverticulum pear-shaped rolled up in one corner or edge of the omentum. The omentum tightly wrapped about and adherent to the diverticulum had produced complete gangrene. The findings, so far, would not account for the obstruction of the bowels and on searching further I found a rent or hole through the upper part of the mesentery through which had passed all of the transverse colon as well as the omentum. There were no adhesions where the colon had passed through the mesentery but the condition appeared to be of long standing. This opening was the size of an egg and after the colon had been drawn up through the opening I closed it. The Meckel's diverticulum and that part of the omentum on which there were gangrenous spots were removed before I replaced the colon.

---

[3] Harris, D. L.: A Clinical Report of Seven Cases of Hydrophobia, The Journal A. M. A., Oct. 25, 1913, p. 1511.

Postoperative History.—The patient, although aged, recovered nicely and is now practically well. The temperature before operation ranged from 96.8 to 97.8 F. Since the operation the temperature has never been higher than 99.4 and the pulse has never been above 84.

THE SPONGE COUNT

P. E. Truesdale, M.D., Fall River, Mass.

Few surgeons of large experience have escaped the humiliating experience of leaving a sponge beneath the abdominal incision for a longer period than intended. Even this cautious and fortunate minority have without question been harassed by a late, unnecessary exploration of the abdominal cavity for a missing sponge subsequently found concealed somewhere else in the operating-room. Surgeons now rarely place sponges entirely within the abdominal cavity without attaching a hemostat to the gauze or a connecting strand of tape. This practice is not universal, however, and one finds the system of following up sponges exceedingly varied. In many operating-rooms a nurse, known to be trustworthy, is assigned the responsible duty of guarding laparotomy sponges. She is expected to count her sponges repeatedly for purposes of verification. This entails a loss of considerable time and is not a sufficiently strong insurance for the surgeon against the accident, since there are many instances on record in which the nurse in charge had proved an efficient guardian for many years, and then experienced a single failure. Since the adoption one year ago of a simple method of control worked out by Dr. R. W. French and myself, we have enjoyed a freedom from any embarrassment in the sponge count. We use sponges which measure a yard in length and 2 and 4 inches wide, respectively. To the end of each is securely sewed a piece of narrow tape 8 or 10 inches long. To this the nurse ties a numbered metal check the size of a silver dollar, before the sponge is delivered to the surgeon for use. Thus it becomes a very simple matter, toward the end of an operation, with the sponges arranged consecutively on a separate table, for the nurse to know that every sponge is in her possession.

Asthmatic Attacks Due to Irritation of Buried Tonsils.—Miss M. F., aged 26, a nurse in one of the hospitals, was sent to me, March 19, 1913. The family history was negative. She had suffered frequent congestion, "colds" and digestive disturbances. Her present trouble commenced about three years ago when she began to suffer from violent asthmatic attacks. These attacks occur both summer and winter, but are worse in the autumn and early winter. She nearly lost consciousness in some of the attacks. She had been treated for asthma with all the ordinary remedies without result. Nothing abnormal was found in the chest or abdomen except slight emphysema. During the attacks typical asthmatic findings were elicited. The urine was normal and vaginal examination showed nothing of note. Examination of the nose showed a quite marked deviation of the septum to the left, but the turbinate was not pressed on. The applicator produced no particular irritation. Examination of the throat showed the tonsils of fair size but diseased and buried. When these were touched with an applicator a violent attack of coughing and sneezing lasting twenty minutes or more occurred. A similar attack recurred the next day when the application was repeated. The next day I removed both tonsils under general anesthesia and the patient has been free from the asthmatic attacks ever since, a period of nearly six months. I believe that a great many cases of "hay-fever" and asthma are due to reflex irritation from the nose, throat or ear. I have never had any other case due to tonsil irritation.—W. T. Patton, M.D., 1109 Maison Blanche Building, New Orleans.

A SIMPLE METHOD OF RECORDING VAGINAL DISCHARGES

Siegfried Figueroa, M.D., Merida, Mexico

Having read with interest Mcfarlane's article[1] on "A Graphic Menstrual Chart," I tried to introduce her method of graphically recording the patient's menstrual history in the gynecologic ward of the Hospital O'Horan of this city, of which I am the surgeon. I soon found that it was difficult to keep a daily record of the menstrual state of all the patients because it was necessary to ink one or more square spaces of each chart every morning. Furthermore only blood, clots and pain could be recorded. Therefore I ventured to formulate another method which would permit at the same time the recording of other vaginal discharges, such as simple leukorrheic, serosanguineous, mucopurulent or watery, in a simpler way.

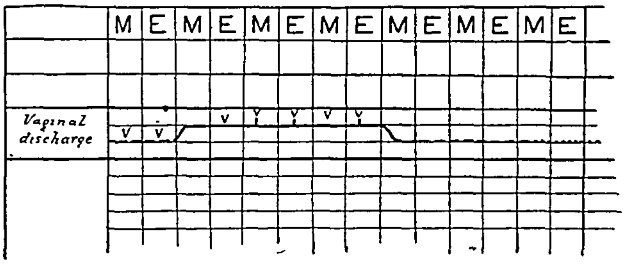

Chart record of a menstrual vaginal discharge indicating a scant serosanguineous discharge accompanied by pain during the first day, a moderate hemorrhagic discharge with pain and clots during the three following days, then a scant serosanguineous discharge beginning in the evening of the fifth day and persisting during the sixth till early in the morning of the seventh, and finally a scant leukorrheic discharge.

To that end I reserved the three spaces corresponding to the one hundred and seventh degree of our temperature chart to the vaginal discharge records. Taking the line of that degree as normal, that is to say, as the point of no discharge whatever, the next line as that corresponding to a scanty flow, the third to a moderate and the last one to an abundant flow, I had under control the amount of the discharge. Its nature I represented in the following fashion: a leukorrheic discharge as a dotted line, a watery discharge as an undulating line, a mucopurulent discharge as a line of alternate dots and dashes, a serosanguineous discharge as an interrupted line and a hemorrhagic discharge as a full line. To indicate clots I used a small perpendicular line falling over the full one representing hemorrhage, and to indicate pain I employed two small converging lines forming an angle just over the line representing the discharge, or alone when there was none. This method has given me perfect and easy control of the genital history of my patients. The accompanying chart illustrates what I have tried to describe.

Calle 59, Numero 488.

Leprosy After Two-Year Incubation Period.—The father of the patient, V. T., now aged 31, Filipino, native of Laguna Province, was admitted to the Culion Leper Colony Aug. 10, 1908, with the clinical diagnosis of tubercular leprosy, microscopically positive. The mother of the patient, G. T., Filipina, now aged 37, native of Bataan Province, was admitted to the Culion Leper Colony Feb. 10, 1910, with the clinical diagnosis of mixed tubercular and anesthetic leprosy, microscopically positive. The patient, a girl born at Culion, May 15, 1911, an inmate of that institution to date, when examined, June 30, 1913, presented no clinical evidences except slight reddening of the cheeks over the malar bones and reddening of the lobes of the ears. Those especially versed in the diagnosis of leprosy would probably regard this reddening as due to leprous dermatitis. Microscopic specimens prepared from scrapings from the cheek and the septum of the nose were positive for leprosy.—Victor G. Heiser, M.D., Director of Health, Philippine Islands, Manila.

Therapeutics

CALCIUM

This element, owing to recent investigations in physiology and pathology, has become of interest therapeutically. Its relationship to the solid tissues of the body has, of course, long been known, but its relationship to the functions of the body, especially to those of the nervous system, has only of late years been investigated or understood. The young child cannot properly grow and the bones do not normally develop if long deprived of calcium. An adult has various functional, and at times pathologic, disturbances from such deprivation. Again, a person may not be deprived of calcium, but may have such chemical disturbances that he loses calcium more rapidly than he can metabolize it, thus suffering actual deprivation. Certain conditions are immediately improved and may be soon cured by the proper administration of calcium. Therefore, a careful study of this interesting subject is therapeutically pertinent.

We are more and more coming to understand that condition of the body which may be termed a hyperacidity, or at least a lessened alkalinity, especially of the blood. So-called acidemia (perhaps a misnomer, as the blood never reaches the point of acidity before a patient dies) is now known to be the terminal condition of many diseases, and is not limited to diabetic coma. The final serious outcome in persistent vomiting, starvation from any cause, gastric intolerance following surgical operations, the vomiting, diarrhea and marasmus of infants, and perhaps the final disturbances of nephritis, is more or less due to general hyperacidity. Imperfect excretion of acid or acid salts by the kidneys or bowels will probably sooner or later cause serious functional and perhaps organic disturbances, and certainly some degree of denutrition. With such diminished excretion of acids the alkalies of the body are more or less neutralized and lost to the tissues, even if not excessively eliminated. The immediate result of such a diminution of alkaline salts is serious disturbance of the nervous system. Many gastro-intestinal troubles in babies and children are due to an excess of acid and a diminution of alkalies.

The symptoms of such systemic hyperacidity (whatever the disease) are those of fever, that is, increased temperature and pulse-rate, restlessness, insomnia, gastro-intestinal disturbance, and often nausea and vomiting. Gastric tetany seems to be due to the diminished alkalinity of the nerve-cells or nerve-tissue, and it has been pretty conclusively shown that ordinary tetany is due many times to parathyroid disturbance, which is really the result of a calcium insufficiency. The lack of calcium also seems to be in evidence in many instances of infantile convulsions, especially in spasmophilia and acute nervous irritability. It may be a cause of meningismus in typhoid fever or other serious infections, and, perhaps, is one of the causes of epilepsy, or of an epileptic convulsion. Even in puerperal eclampsia when the kidneys are not found seriously insufficient, a considerable diminution of the alkalies, especially of the calcium salts, may be a factor in causing the convulsions.

It need only be suggested that the withholding of starches and carbohydrates and the feeding of meats and such proteins as tend to hyperacidity will always increase the tendency to eclampsia, epilepsy, spasmophilia and convulsions, to say nothing of such acid-producing food as a cause of increased bowel toxemia and more irritation of insufficient kidneys.

Many of the glands which have an internal secretion — the thyroid, parathyroids, ovaries and testicles, pituitary and the thymus in infancy and childhood — seem to take part in normal lime metabolism. The thymus contains a large amount of nucleoprotein and phosphate radicals, and, it would seem, must have a great deal to do with the formation of calcium and phosphate salts for the normal growth of bone. When the child has reached the age of puberty, at which time the largest part of its bone growth has been completed, this gland atrophies, and probably the thyroid assumes, besides its own work, such necessary metabolic work as the thymus has been doing.

The relationship of the pituitary to calcium metabolism has not been determined, but its relationship to enormous bone growth, as in giantism and acromegaly, has been proved, and this extra growth cannot occur without a deposition of an abnormal amount of calcium bone salts.

In excessive activity of the thyroid gland and the disturbances so well recognized as Graves' disease, with its hypernervous excitability, there is always improvement if meats and other acid-forming foods are removed from the dietary, and a quieting effect on the central nervous system and apparently a diminution in the activity of the thyroid gland is produced if calcium salts are given. Whether these salts simply soothe the central nervous system, or whether an excess of them quiets the activity of the thyroid gland, has not been determined. The action noted, however, is a clinical fact.

Ovarian disturbances have seemed to cause a derangement of calcium metabolism. In many instances osteomalacia has been traced to some ovarian disturbance, perhaps a hypersecretion, as such conditions have followed too frequent pregnancies. In some cases the disease has been cured by removal of one or both ovaries.

The relationship of the testicles to calcium is not known, but analogy indicates that they probably take some part in the metabolism of this necessary element. In some animals, from which the testicles have been removed, there has been a retention of phosphates and of lime, and the likelihood of convulsions is less in castrated animals than in those uncastrated, which is one more proof that an excess of calcium in the system seems to inhibit the convulsive irritability of the central nervous system.

The deleterious effect of an excessive amount of magnesium and a deficient amount of calcium in plant life has long been known. In the presence of an excess of magnesium the growth of a plant is slow and imperfect and the plant may die, while with a diminution of the magnesium and the addition of a suitable amount of calcium, the plant will grow normally and vigorously.

It has long been inferred, and has not been experimentally denied, that an acid excess in the system tends to *neuralgias, neuritis and neurasthenic conditions.*

In diabetes mellitus the alkalinity of the blood is known to be greatly diminished. One of the consequences, if the diminution is not sufficient to cause coma, is the production of boils and carbuncles.

PHARMACOLOGY

Lime salts not only form a large portion of the inorganic part of bones and teeth, but they also occur in small amounts (estimated by Schwarz and Bass[1] as 0.01 per cent. of the total amount in the body). According to this estimate, a child weighing 10,000 gm. (about 22 pounds) would have only 0.50 gm. (about 7½ grains) of calcium in its soft parts. It has been found that there is more calcium in the brain before than after birth, and that the amount diminishes as the child grows older. The calcium in the blood has been found highest in the child, and this also decreases slowly with age, being higher in breast-fed than in artificially fed children. Children seem to retain calcium longer than adults, and evidently store it. This also is more in evidence in breast-fed infants than in those who receive cow's milk.

---

[1] Schwarz and Bass: Am. Jour. Dis Child., 1912, iii, p. 15.

It has been stated that it may not be the absence of calcium, but the relationship between sodium and calcium salts that allows nervous irritability, as it seems to be a fact that a diminution of sodium salts and an increase of calcium diminishes nervous irritability. In several instances the calcium has been found diminished in the brains of children who had died from tetany.

Even the soluble salts, Cushny states, are absorbed with difficulty, and the calcium salts "precipitate colloids such as proteins, in much more dilute solutions than the alkalies, and the precipitate is not redissolved by dilution with water." While the calcium salts retard the absorption of fluid from the intestines, they still do not cause catharsis as do the magnesium salts. In fact, lime salts are many times constipating.

Like iron, a very small amount of calcium is absorbed in the alimentary canal, the larger portion, whether in the form of soluble or insoluble salts, passing off in the stools. Even a considerable portion of the calcium that is absorbed is excreted by the epithelium of the large intestine and also passes off by the bowels, only a small proportion, in normal conditions, passing off by the urine. L. B. Mendel has shown that the administration of calcium will increase the elimination of magnesium in the urine, and similarly, magnesium, when absorbed, leads to a larger excretion of calcium. The calcium so excreted occurs mostly as a phosphate.

Jacoby and Eisner,[2] in articles on the influence of calcium salts on the kidney, show that in experimental glycosuria in animals the feeding of calcium causes a diminution not only of the sugar output, but also of the nitrogen. In fact, according to Jacoby, all excretion from the kidneys, except water, was diminished by calcium feeding, and later the animals died. An increased amount of calcium in the food or administered as a drug will decrease the phosphates in the urine, and also its acidity.

Eisner found in a number of instances that the feeding of calcium to patients who had nephritis caused serious retention of substances which should be excreted by the kidneys, that not only was the albumin reduced in amount, but also the total nitrogen. He therefore believes that calcium, in any amount, should not be given to nephritic patients.

It has been many times stated that in tuberculosis or in the pretuberculous stage an increased amount of calcium is lost both in the urine and feces. In fact, a demineralization has been thought to be a forerunner of the development of tuberculosis.

While lime is present in so many articles of food that lime starvation is not frequent, unless deliberately planned (it should be recognized that a meat and bread diet may cause lime starvation), still some chemical condition may prevent the lime of the food from metabolizing to its proper usefulness in the body. This same chemical or biologic mistake occurs in chlorosis when a young girl receives food rich in iron and yet becomes anemic. Or, as previously suggested, some internal secretion may be so disturbed as to produce a waste of calcium by causing an increased output of lime from the body. Any such deprivation is of course more serious in infants and young children than later in life.

Though it has been shown that lime is not necessary to the formation of fibrin, the fibrin ferment will not be formed and coagulation of the blood will not occur, except when calcium salts are present. While lime is necessary for the normal coagulability of the blood and to lessen the tendency to hemorrhage, still the administration of lime salts by the mouth will not quickly hasten the normal clotting. Such metabolism is slow and cannot be rapidly pushed by giving large amounts of lime. Von den Velden,[3] however, has recently shown that the administration of calcium lactate (from 4 to 6 gm., or from 1 to 1½ drams a day) for five days or more will stop such bleeding as occurs in scorbutus.

It has been shown that calcium will strengthen a weak heart muscle, and clinically many a weak heart may be made to improve by adding calcium to the medication, when such improvement has not occurred before.

It has long been clinically noted that many children suffering from diarrheas are benefited by small doses of calcium, and it may be true that the acute irritability of the nervous system which we term chorea (whether this disease is or is not caused by an infection similar to acute rheumatism) may be due to an increased loss of calcium by the body. Certainly calcium seems to be of benefit in quieting the nervous system of these patients An enlarged thyroid gland in young girls and women is often reduced to normal size by the administration of small doses of calcium.

LIME IN TUBERCULOSIS

Besides the physiologic determination that there is loss of lime in tuberculous and pretuberculous patients, for perhaps more than fifty years it has been thought that the hypophosphites were of value in pulmonary tuberculosis; that they not only increased the appetite and nutrition, but also aided specifically in the healing of the tuberculous lesions. Chemically, however, it has been shown that the hypophosphites leave the body almost unchanged and non-metabolized. It is supposed that it is the phosphorus element in the hypophosphite combination that is of special value, but if any one of these salts is of value it is the calcium hypophosphite, and the value of even this is doubtful, as the calcium is likely to be precipitated in the intestine as phosphate or carbonate and excreted in the feces.[4]

Calcium phosphate is perhaps the most valuable biologic salt in cellular development, but unfortunately it is not a simple matter to supply a deficiency in this salt, as administration of calcium phosphate as such will generally not be effective. The calcium molecule in whatever form presented must be broken up and rebuilt in the blood and tissue.

Forced feeding of tuberculous patients and the enormous amount of eggs and milk once given such patients are not now considered advisable by a large number of physicians who are specializing in the treatment of pulmonary tuberculosis.

(To be continued)

THE FOOD-VALUE OF FISH AFTER COLD STORAGE

The imperative need of some safe, efficient and hygienic method of conserving putrescible food materials for human consumption at periods long after they leave the source of original production is being more forcibly brought home to American purchasers and producers every year. The suitability of some of the procedures employed has been referred to in The Journal from time to time. The value of desiccation has doubtless been underestimated in many instances in the past,[1] although it has many obvious limitations, such as the alteration of the natural flavor of food products occasioned thereby in some cases and the relative expense of this mode of food preservation in others. Sterilization by heat is applied in many departments of the food industries with eminent success. The use of chemical preservatives has received a wholesome check through the stricter limitations which modern legislation is placing on the introduction of foreign compounds into food products, so that in this direction, too, the prospect of permissible expansion is not promising. Much careful consideration has therefore been directed to the possibilities and the limitations of cold storage as a mode of food preservation, from both the hygienic and the economic point of view.[2]

Although the preservative effect of low temperatures on foodstuffs has long been known, the study of the chemical changes which the products may undergo during prolonged refrigeration has not been vigorously prosecuted until a comparatively recent date. In this work the Federal Bureau of Chemistry has been particularly active, and numerous statistics have been published in regard to the behavior of meats, poultry, eggs, butter, etc., under the varied conditions of cold storage applied in the trade at the present time or proposed for introduction. There are, however, few data available in regard to the effect of cold storage on the chemical composition of the flesh of fish, although this method of preservation has been used longer for fish than for many other foods products now so preserved. The importance of detailed and trustworthy information as to this effect is the more evident in relation to fish because they are commonly recognized to be peculiarly prone to decomposition.

A plant for the freezing of fish by means of salt and ice was established in New York City as early as 1861.[3] The frozen-fish industry in America had its real beginning in the early nineties, but progressed very slowly because of the long-maintained prejudice against cold-stored products and frozen fish in particular. The development of the ammonia process for the production of low temperatures has been one of the chief factors in fostering the cold-storage industry. At present, many varieties of fish are refrigerated. Each firm has its own method of freezing fish, but the general practice seems to be to freeze the fish, dip them in water, and refreeze in order that they may be completely encased in ice. They are then stored at a temperature of — 16 C. (3.2 F.). The coating of ice, which is renewed as occasion requires, prevents loss of water due to surface evaporation.[4]

The outcome of an investigation conducted in the Biochemical Laboratory of Columbia University at the College of Physicians and Surgeons, New York City,[5] on the composition of the flesh of a typical species — flounders — with respect to the possible changes induced by current trade methods is gratifying. We need not review the chemical details and the criteria, such as estimations of alterations in the proportions of nitrogenous constituents, the development of reducing substances, the hydrolytic changes in the fats, etc., which were applied by competent biochemists. Their contention, well justified by the data presented, is that there is no evidence whatever of any depreciation in the nutritive value, or any change in the sanitary character, of the fish at any time during two years of cold storage. The data for the yield of ammonium nitrogen — an especially characteristic indication of microbial changes — showed a constancy that excludes appreciable alteration through bacterial decay, and evidences of autolytic changes were likewise not forthcoming. Even the culinary virtues and palatability of fish kept frozen thus long were not impaired.

Convincing as these studies are of the excellent possibilities of preserving fresh fish by the freezing process, they must not be allowed to disguise the fact that they do not give a clean bill of health to animal tissues removed from cold storage and exposed until sold or even kept iced in a common refrigerator. Neither can spoiled food be adequately preserved by any method. It is unfortunate that the efficiency of useful processes is sometimes impugned by unjustifiable applications of it. This has been true of cold storage.

A NEW TREATMENT FOR CEREBROSPINAL SYPHILIS, INCLUDING TABES AND PARESIS

While antisyphilitic treatment in the early forms of syphilis of the central nervous system has been as successful as in syphilis in other parts of the body, the later forms as tabes and general paresis have been utterly intractable to antisyphilitic measures. In early tabes an arrest of the progress of the condition might be hoped for, but in paresis the prognosis has been hopeless. A method for successfully treating these forms of syphilis would be an achievement of the first rank in therapy.

The discovery of salvarsan raised hopes that it would be effective in late stages of cerebrospinal syphilis. Its failure to produce results in this condition comparable to those produced in other forms of syphilis contributed support to the belief that these disorders are not syphilitic, but parasyphilitic—a belief already held by many clinicians — and the outlook seemed as hopeless as before. With the demonstration of the *Spirochaeta pallida* within the substance of the central nervous system in tabes and paresis the belief that these are not active syphilitic processes become untenable, and the question again arose why these conditions are so resistant to the usual antisyphilitic treatment. An explanation is offered in the supposition, not unsupported by experimental evidence, that the tissues and fluids of the cerebrospinal organs absorb very little if any of certain substances introduced into the circulating blood. For example, meningitis is not perceptibly benefited by intravenous administration of antimeningococcus serum, while intraspinous injection gives definitely beneficial results. The reason for this was not clear until delicate tests showed that antibodies thus introduced do not appear in the cerebrospinal fluid even though present in abundance in the circulating blood.

That antisyphilitic substances may in a similar way fail to reach the tissues of the brain and cord when introduced in the ordinary manners is not improbable. The injection of salvarsan and neosalvarsan directly into the cerebrospinal canal in animals produced directly harmful results. Swift and Ellis[1] found that when a quantity of blood was withdrawn from the veins an hour or more after injection of salvarsan, the serum separated and heated to 56 C. (132.8 F.) and then injected into the cerebrospinal canal, no ill effects followed, and patients so treated were decidedly benefited. Further reports of a most encouraging nature are found in two articles in this issue of The Journal. Hough presents the results of this treatment in six cases, together with curves representing the cell and globulin content of the cerebrospinal fluid and the Wassermann test on both the serum and cerebrospinal fluid at intervals during the treatment. McCaskey records histories of seven cases similarly treated. Both give details of technic, and both report marked improvement and no ill effects resulting. This method for administering salvarsan at least opens two avenues of attack where one existed before, and the treatment of syphilis of the central nervous system becomes proportionately more hopeful. Reason for hope is the greater as laboratory tests and painstaking clinical methods make early diagnosis possible, enabling treatment to be instituted before degenerative changes in the brain and cord have become advanced. Further reports on the treatment of cerebrospinal syphilis by intraspinous injection of "autoserosalvarsan" will be awaited with eagerness.

"CURE" OF RHEUMATISM AND JOINT-TROUBLE

One of the commonest affections that the physician has to treat is called "rheumatism" by the non-medical and by probably the majority of physicians alike, as the symptoms consist of pains and aches, sometimes rather vague, but often acute and definitely located in or around the joints. Not infrequently a distinct amount of disability goes with the affection; the ordinary use of an arm or a leg is uncomfortable or impossible. The cases occur in all forms and the patients are of all ages, though the condition develops much more commonly beyond middle life than in the earlier years.

These cases, grouped together under a generic term, are usually considered as due directly or indirectly to some disturbance of metabolism, some absorption of toxic material from the intestines or some poisonous substance elaborated in the blood. For a long while it was almost universally agreed that these symptoms were due to the presence of uric acid in the system consequent on a disturbance of nitrogen metabolism. A number of remedies for this condition have been on the market for many years and have obtained a reputation because of the number of cases of this kind in which they were said to cure. The uric acid explanation began to lose its vogue about twenty years ago and now there are few well-informed physicians who accept it as explaining these cases. The remedies directed against uric acid, however, still continue to be used in large quantities, sometimes by old-fashioned physicians, but much more by the laity, which loves to roll under the tongue that delectable morsel of pseudoscience, the term "uric acid diathesis."

As uric acid went out, the question of some other disturbance of nitrogen metabolism took its place. We heard much of the purin bodies and of various disturbances of protein digestion, and, above all, of improper protein absorption, as the source of the symptoms that are so common and form so large a part of the occupation of the general practitioner of medicine. A number of remedies directed particularly to the amelioration of these disturbed conditions and the improvement of the internal nutrition were put on the market. Most of them exhibited evidence of their usefulness by "cures." At present, wide-spread attention is attracted to a whole series of such remedies that are claimed to be almost specific in their action on rheumatic conditions, that is, the pains and aches in the neighborhood of joints supposed to be rheumatic.

---

[1] Swift, Homer F., and Ellis, Arthur W. M.: The Treatment of Syphilitic Affections of the Central Nervous System with Especial Reference to the Use of Intraspinous Injections, Arch. Int. Med., September, 1913, p 331.

The most interesting thing about these conditions is the history of their successful treatment, not for a generation or so, but for two or three centuries. Patients complaining of vague pains around joints and in groups of muscles in various parts of the body have supplied a large proportion of the "cures" attributed to remedies and treatments at first heralded as marvelous and later proved ineffective. In its original form the Leyden jar was scarcely more than a toy. In Europe many healers of disease produced wonderful effects with it in just this class of patients, the old persons with chronic diseases of the joints and muscles. A little later, when the first electric machine that would give a continuous series of sparks was invented, this was employed in such cases, with wonderfully good results. Almost needless to say, the physical effect of the electric machine on the human body was so little as to be quite negligible, but it worked a great many cures. A little later in the eighteenth century, Galvani made his demonstration of the twitching of a frog's leg when two metals in contact with each other are applied to the nerve and muscle. His demonstration led to a prolonged scientific discussion as to the relationship between electricity and vital force, with a great deal of emphatic assertion on the part of certain scientists that at last the secret of life had been discovered—we are always discovering the secret of life—and then a new field of therapy was open. Elisha Perkins effected many "cures" by stroking patients with two pieces of metal, which he called "tractors." His expulsion from the medical society of Norwich, Conn., on the ground that there was no value in his tractors only gave the astute Yankee from the Wooden Nutmeg State an opportunity to advertise that the medical profession was jealous of him and wanted to put him out of business for fear he would cure all its patients.

When Father Maximilian Hell, the professor of astronomy at Vienna, became interested in the application of magnets as a new curative agent, the patients under his observation who were "cured" were usually those suffering from vague pains and aches in the neighborhood of joints or in large groups of muscles. His greatest success was with the chronic pain in the back that used to be attributed to kidney disease. It has been well said that except in very acute cases the kidneys give pain only in the newspapers; but the number of remedies, kidney plasters and applications of all kinds as well as internal medication without end that have benefited these pains in the loins is legion. Father Hell made his "cures" by applying magnets shaped like kidneys. Mesmer, pursuing his medical studies in Vienna, was attracted to Father Hell's results, and the consequence was his own development of special methods, including the famous "battery" consisting of bottles filled with iron filings connected by wires and placed beneath the water in a tub from which wires led out to be applied to the patients. The modern Oxydonor and Oxypathor are not more subtle fakes, and, though they have the advantage of a century's development in the art of advertising, they do not seem to be able to report so many "cures" as did that prince of charlatans. Mesmer made very little use of what we call mesmerism, and never produced the hypnotic sleep, but achieved his results by the use of supposedly wonderful physical effects.

When hypnotism began its most recent vogue in the latter part of the nineteenth century, it was taken up by Bernheim of Nancy, because he had seen a patient with sciatica, who for years had been coming to his clinic and for whom little could be done, cured by hypnotism under the care of Liébeault. This led him to study Liébeault's methods, and the Nancy school of hypnotism resulted. It might be added that a great many of the patients who proclaimed themselves benefited under Dowie's care, or cured by poor Schlatter at the end of the nineteenth and the beginning of the twentieth centuries, were sufferers from these chronic painful conditions, usually complaining of vague aches in the neighborhood of joints or in large groups of muscles.

Evidently these patients have always been cured by anything that deeply and favorably affected their minds. It is not that they have no real ailment, but that their consciousness, focused on some slight physical discomfort, has room for little else, and hence keeps them miserable until some distraction is obtained. Such patients go around from physician to physician, apparently benefited temporarily, but not relieved from their aches, and indeed declaring often that it was only their anxiety for a cure that made them think for a time that they were better under the new physician. They help to swell the immense number of persons who go to quacks of all kinds, manipulators, chiropractics and the like, and then proclaim themselves greatly benefited. Evidently there is no class of affections with regard to which more care as to the reporting of "cures" must be exercised than these so-called rheumatic conditions. Manifestly, too, there is nothing that shows the lack of significance of "cures" so much as does this group which has been the subject of "cures" of all kinds for centuries, each "cure" in turn proving after a time to have no physical effect, though at first it seemed to be a wonderful remedy.

NEPHRITIS FROM PROTEIN INTOXICATION

The observation, in cases of protein intoxication, of fever, albuminuria, edema, urticaria and other symptoms of nephritis led Longcope[1] to make clinical and anatomic studies on the course of experimental protein intoxication in animals. The purpose was to determine whether nephritis or other demonstrable injury to the body-cells might in some cases result from repeated anaphylaxis or protein intoxication. Experiments were made on series of animals of different species, including guinea-pigs, cats, rabbits and dogs. The animals were first sensitized by injecting large quantities of foreign protein—in these experiments horse-serum and white of egg—intraperitoneally, intravenously, subcutaneously or by a combination of these routes. About three weeks later the animals were reinjected with such quantities of the foreign protein as to produce severe symptoms of anaphylaxis, but not to cause death. The behavior of the different species of animals was observed to correspond to the symptoms which other observers have described as characteristic of anaphylactic shock. The injections of toxic doses of protein were repeated at short intervals and finally the animal either was given a fatal dose or was killed and necropsy made. The urine following such treatment usually showed albumin, detritus, and hyalin and granular casts. Changes were observed in many organs: The peritoneal and omental tissues were thickened, opaque and whitish, and suggested the occurrence of a chronic inflammatory process. Eosinophilia and the presence of small round cells and fibroblasts were frequently observed. The lungs of the guinea-pigs showed small bronchopneumonic patches and peribronchial infiltration containing many eosinophils. The livers of the rabbits and cats showed areas of periportal necrosis and portal cirrhosis of low grade. Similar areas of necrosis were also observed in the myocardium in each species, but most marked in the rabbits. Scars of healed necroses and sometimes diffuse chronic myocarditis were found. Renal changes, however, were most frequent, occurring in 24 of 29 rabbits, in 7 of 12 cats, in all of 13 guinea-pigs and in 10 of 12 dogs. When the animals died of acute intoxication the parenchyma was the seat of extensive cloudy swelling, congestion and often edema. Sometimes both cortex and medulla showed areas of necrosis in which the cells lining the tubules were desquamated, and the areas surrounded by zones of round-cell infiltration. When the process was more advanced the changes were more extensive, and in addition to the necroses and inflammatory reaction there was a distinct increase of interstitial connective tissue. Often the tubules were atrophied and contained hyalin casts, and some glomeruli showed complete hyalin degeneration. Occasionally there was proliferation of the capsular epithelium and swelling and thickening of the capillary tufts.

The finding of such lesions is definitely characteristic of nephritis in different stages, and Longcope states that the most advanced changes were found in the animals in which the intoxicating injections had been received over the longest periods of time. In order to exclude the possibility that the nephritis was of spontaneous occurrence and not due to the repeated protein intoxication, a large number of untreated animals were examined for similar lesions; also three dogs were tested by comparing a portion of kidney removed by operation after the animal had been sensitized, with a portion taken at necropsy after the dog had recovered from the operation and had received the intoxicating injections of foreign protein. By such tests Longcope was convinced that the nephritis was not of spontaneous occurrence, nor was it due to the process of sensitization.

The experiments are of interest as demonstrating a method by which nephritis may be produced experimentally; but their chief significance lies in the relationship which they so strongly suggest between nephritis and anaphylaxis — that is, parenteral protein intoxication. This, together with the fact that the toxemia of infectious diseases is now regarded as an anaphylactic manifestation, suggests a plausible explanation of the occurrence of nephritis, cirrhosis and other lesions associated with infectious and toxic processes.

RECENT PITUITARY FINDINGS

Comparative physiology has more than once thrown interesting sidelights on the functions of the human organism. Cushing and Goetsch[1] of the department of surgery in the Harvard Medical School have called attention to the striking fact that the phenomena of hibernation which are regularly observed in certain animals like the woodchuck, strikingly resemble the train of symptoms coupled with retardation of tissue metabolism and with inactivity of the reproductive glands which attends experimental states of hypophyseal deficiency and is equally characteristic of clinical states of hypopituitarism. The more notable of these symptoms are a lowering of body temperature, slowing of pulse and respiration, fall in blood-pressure, and somnolence together with a tendency, in the chronic cases, toward an unusual deposition of fat.

The Boston investigators have now found, in conformity with the foregoing parallelism of symptoms, that in the dormant period of a series of hibernating animals the pituitary gland not only diminishes in size but also undergoes extreme histologic alterations, chiefly evident in the cells of the pars anterior, which completely lose some of their most characteristic differential staining features. At the end of the dormant period the gland enlarges and the cells regain their characteristic staining properties. Cushing and Goetsch remark that on the basis of this observation hibernation may be ascribed to a period of physiologic inactivity, possibly of the entire ductless gland series, but certainly more especially of the pituitary body, not only for the reason that the changes in this structure are particularly apparent, but because deprivation of the secretion of this gland alone of the entire series, is known to produce a train of symptoms comparable to those of hibernation.

[1] Cushing, H., and Goetsch, E.: Hibernation and the Pituitary Body Proc. Soc. Exper. Biol. and Med., 1913, xi, 25.

In connection with the assumed, and in part demonstrated, relations of the hypophysis to the reproductive glands, further new experimental findings of these well-known investigators of pituitary functions deserve a reference here.[2] They indicate that administration of pituitary extract, and particularly extract of the pars anterior, has a markedly stimulating effect on the growth and development of the reproductive glands in young animals of both sexes, as evidenced by histologic examination. The converse of this is seen clinically in cases of hypopituitarism in man. Furthermore, in the animals investigated, extract of the pars anterior tends to cause early and frequent breeding; whereas the posterior lobe extract has no such effect and, in common with ovarian extracts, apparently does not stimulate sexual development. Observations of this character obviously will help to furnish the scientific basis for a rational correction of defective hypophyseal functioning as well as the intelligent use of extracts of the organs in therapeutic ways.

Current Comment

RADIUM THERAPY IN CARCINOMA

The recent somewhat sensational announcements of the benefits of radium therapy in carcinoma have given rise to renewed hopes which may perhaps be doomed to later disappointment. Very timely is a report by Sparmann[3] concerning the after-history of cancers treated with radium. He discusses fifty-three cases which were reported some time ago. The figures have now been revised to give conditions as they exist to-day. Of the eleven cases previously recorded as improved, three are transferred to the list of cured, two have resumed their malignant course. and two patients are dead. In six cases previously reported as slightly improved, the condition is much aggravated in five. Of a total of fifty-three patients, eleven have died since the treatment; in six the tumor has disappeared; in five the conditions seem improved; in seven the condition is aggravated, and in the others treatment was not continued because the condition of the patients had become worse. These results show that radium is a remedy of use in the treatment of cancer, "but," as Sparmann says, "it is not a sovereign remedy." The radium rays, he continues, sometimes extend beyond the cancer into sound tissue and wreak damage there, and thus are liable to be harmful. In non-operable cases Sparmann sees a use for radium. "It belongs undoubtedly and justly," he says, "to the modern equipment of medical science in its fight against malignant tumors." He concludes, "We shall not win brilliant victories with this new weapon, but it will help us to gain step by step in our persevering and incessant siege of cancer."

RACE BETTERMENT

If it is true, as H. G. Wells makes his hero declare in one of his recent novels, that there is a collective mind apart and distinct from individual intelligence, then it must be admitted that the social intelligence of to-day is concerned as never before with the future and with the good of coming generations. Of this, the Conference on Race Betterment, just held at Battle Creek, Mich., is a striking illustration. Whatever one may think of the individual views expressed, or of the immediate, concrete results of such gatherings, the fact is in itself significant that such a conference, extending over five days and attended by thousands of people. is possible. Never before in the history of civilization have there been so many men and women who were earnestly, sincerely and unselfishly laboring for the general good. One may criticize their reasoning, dissect their statistics or draw from their premises entirely different conclusions, but the important fact remains that such conferences, which are becoming increasingly frequent, would have been impossible and practically inconceivable a generation ago. The pessimist and the critic see in such gatherings only another symptom of universal unrest and discontent. The optimist sees in them faintly foreshadowed the dawning of the age of which Tennyson sang, when each man's good shall be all men's aim. The purpose of the Battle Creek conference, as officially stated, was "to assemble evidence as to the extent to which degenerative tendencies are actively at work in America and to promote agencies for race betterment." Under the first head were papers on apparent increase in degenerative diseases, the causes of the declining birth-rate, crime, deterioration of civilized women, factory degeneration, alcohol and tobacco, social evil, and delinquent and defective children. On the constructive side were discussions on eugenics in many of its phases. The program impressed one as being overloaded on the degenerative side — possibly because of an overemphasis of the subject at the present time — and as too much given over to a discussion of the past and present conditions rather than of constructive plans for the future. The general effect left on the mind of the listener was that the many papers and addresses, most of them excellent in themselves, were not correlated and were written often from conflicting, if not contradictory points of view, while many of those in attendance impressed the careful observer as being earnest rather than informed, and zealous rather than discriminating. The impressive, undeniable fact, however, is that they were there. It is possible to-day. for the first time in the history of civilization. to call and to hold a conference to discuss not time-worn dogmas or even present-day needs, but future possibilities. From this point of view, such conferences must command the careful attention of the student of social development.

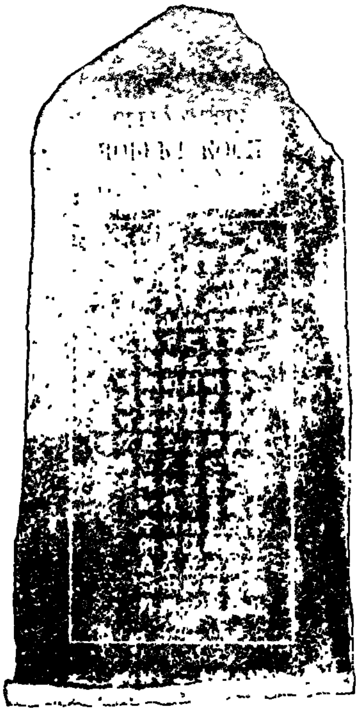
A MONUMENT TO KOCH IN JAPAN

Recently in Berlin there was held a silent memorial to Robert Koch on the day when he would have attained his seventieth year. Such a memorial is significant of the great love which the German people have for this noted scientist. Equally significant is the erection of a monument to the great benefactor at a spot in Japan to which Koch often went to enjoy the view. The monument, which we reproduce,[1] and the language on it, are typically Japanese. The translation by Mrs. Koch of the Japanese inscription describes best the circumstances of its erection. At the top is the inscription in German: "A Monument to Robert Koch, whose favorite resting-place this was." The longer inscription in Japanese reads as follows:



Monument erected to Koch in Kamakura.

> In the forty-second year of the reign of Meidji, in the seventh month, the great German physician and teacher, Koch, professor in Berlin, came to Kamakura. He pitched his tent here on the Mountain of Spirits and morning and evening he walked about with Professor Kitasato to enjoy the beauty of the mountain and the temple. After a time he returned to his western home where he died soon after. The owner of the mountain has joined with others in erecting this monument in commemoration of Koch's beloved spot. This place was chosen around which the waves of the sea dash and storm, and above which gleams the snow-white peak of Fuji-no-yama, already renowned in older times through the great battle of the famous Japanese hero, General Nitta. Here, by Inamura-saki, he cast his sword into the sea, and hither came the great man from across the ocean, looked across to Fuji and loved the place. Therefore, let this stone remain here as a lasting memorial. Written in the first year of the reign of Taisho, in the ninth month, by Nagasaka-Shuki.

RACE SUICIDE

The lowering of the birth-rate in certain foreign countries is giving rise to various schemes for increasing the size of families. It has been suggested in France that all estates be divided into at least four parts. If the family has sufficient children, each child would receive a portion; if not, the unused portions would be taken by the state. It has also been suggested that large families be exempt from taxation. Now the suggestion is made[1] that the head of each household be entitled to as many votes as there are members of his family: the bachelor one, the childless husband two and the procreative parent three, four or twelve as the case may be. This scheme, it is thought, would probably be effectual. By their voting power, large families would then control taxation and the government, and in time become a lever to adjust the balance of political power. Ultimately there would come a modification of the attitude of the people toward reproduction and child-bearing which would lead to larger families. The imaginative mind can picture a future scene in which the corpulent ward-heeler will lead a proud father to the polls to cast fifteen or twenty votes for a favorite measure, the evidence of his right to do so following happily in the rear, or playing tag around the voting booth.

PHYSICIANS AND CLEANLINESS

In an article in the *Southern Medical Journal,* an abstract of which appears in this issue,[2] Dr. Charles Wardell Stiles severely criticizes certain physicians with whom he has come in contact for a want of cleanliness in their offices, and for lack of careful observance of the rules of general hygiene. He says that inasmuch as physicians constantly advocate health legislation, they should be prepared to set a proper example of cleanliness for the laity. His contention is supported by numerous instances, which he cites, of the shortcomings of physicians in this respect in connection with their offices, their homes and their conduct in public meetings. Stiles' experience is no doubt unusual and his criticism is probably applicable only to the careless few. It is true, however, that physicians should set an example for the public in hygienic matters, and that they should be almost overscrupulously clean for the added reason of safety to their patients. This severe castigation of physicians is valuable therefore in calling again to the attention of physicians the importance of strict personal and practical cleanliness as an aid and example for the public.

Medical News

ILLINOIS

Personal.—Dr. Simon P. Brown, one of the oldest practitioners of Elgin, is reported to be seriously ill at his home. ——Dr. J. Sheldon Clark, Freeport, has returned from Europe.

New Crèche Opened.—The new nursery building of the Bethlehem Crèche at Fifth Avenue and Fifty-Third Street, Chicago, known as the Richard Arthur Wells Memorial, was formally opened with a reception, January 10.

State Board of Health Meeting.—At the annual meeting of the State Board of Health held in Springfield, January 13, the board reorganized, electing Dr. John A. Robison, Chicago, president, as successor to Dr. George W. Webster. The present personnel of the board is as follows: Drs. A. Szwajkart, Chicago; R. D. Luster, Granite City; T. B. Lewis, Hammond;

[2] Stiles, C. W.: Southern Med. Jour., December, 1913, p. 783; abstr., THE JOURNAL A. M. A., this issue, p. 237.

John A. Robison, Chicago; James J. Hassett, McLeansboro, and T. O. Freeman, Mattoon.

A Memorial to Christian Fenger.—A recommendation has been made to the Board of Education of Chicago by the Committee on Buildings and Grounds that a new high school building, now in course of construction, be named the Christian Fenger High School. There are, already, two public grade schools which bear the names of Daniel Brainard and N. S. Davis and a magnificent high school which is a memorial to Nicholas Senn. It is probable that the present recommendation will be approved as an appropriate recognition of the work of this great surgeon, and of his influence on pathologic study and the growth of medical education.

National Guard Changes.—Under the provisions of the new War Department circular, the following changes have taken place in the medical corps of the Illinois National Guard: Col. S. C. Stanton, surgeon-general, has been retired at his own request, with the rank of brigadier-general; Lieut.-Col. George Paull Marquis has been retired at his own request, and Major Jacob Frank, secretary to the surgeon-general, has been appointed surgeon-general, with the rank of lieutenant-colonel. As a result of promotional examinations, December 27, Lieuts. Eli B. Moss and Cornelius A. Leenheer, M. C., have been promoted to captains, M. C., assigned to the First Infantry, and Lieut. Elmer M. Eckard, Peoria, has been promoted to captain, M. C., and assigned to the Fifth Infantry.

INDIANA

Antituberculosis Camp to be Moved.—The antituberculosis camp at Pottawottamie Park, conducted there for several years by the Anti-Tuberculosis Association of South Bend, is to be moved this spring to the site of the new Tuberculosis Hospital for St. Joseph County.

Personal.—Dr. Rollin H. Bunch has been installed as mayor of Muncie.——Dr. and Mrs. C. B. Stemen, Fort Wayne, have gone to Florida for the winter.——Dr. Felix G. Thornton, Knightsville, was knocked down by a team of horses, December 31, and seriously injured.——Dr. William Godfrey Wegner, for seven years health commissioner of South Bend, has resigned and been succeeded by Dr. Henry Edmund Vitou.——Dr. A. E. Rumely, La Porte, has resigned as secretary of the M. Rumely Company.

New Officers.—Indianapolis Medical Society, January 6: president, Dr. Thomas B. Eastman; secretary-treasurer, Dr. Alfred Henry.——Wabash County Medical Society at Wabash, January 7: president, Dr. Walter A. Domer; secretary-treasurer, Dr. Lawrence E. Jewett, both of Wabash.——Fulton County Medical Society at Rochester, January 6: president, Dr. Harley W. Taylor; secretary-treasurer, Dr. Earl Waite, both of Rochester.——Jackson County Medical Society at Seymour, January 1: president, Dr. James M. Shields; secretary-treasurer, Dr. L. Butler Hill, both of Seymour.——Adams County Medical Society at Decatur: president, Dr. Marion F. Parrish, Monroe; secretary-treasurer, Dr. Sterling P. Hoffmann, Decatur.——Madison County Medical Society at Anderson, December 30: president, Dr. Stanley C. Newlin, Anderson; secretary-treasurer, Dr. Etta Charles, Alexandria.

MARYLAND

Campaign for Emergency Hospital.—In a seven-day campaign held at Easton for a fund for an emergency hospital, $40,819.38 was realized.

Church Home and Infirmary.—The Church Home and Infirmary has installed a Roentgen ray department and pathologic laboratories at a cost of about $15,000.

Course in Tropical Medicine.—A course in the study of tropical disease was inaugurated at the Johns Hopkins Medical School, January 9, by Dr. A. W. Sellards.

Meetings.—A meeting of the Baltimore Medical Society was held on Friday, December 19, in honor of Dr. Louis McLane Tiffany, and a portrait of Dr. Tiffany was presented to the Medical and Chirurgical Faculty on behalf of his colleagues, pupils and friends. Dr. Samuel C. Chew spoke of Dr. Tiffany as a colleague and friend; Dr. Ridgley B. Warfield, as a teacher, author and man, and Dr. W. S. Halstead on his place in American surgery.——The officers of the Medical and Chirurgical Faculty of Maryland for 1914 are: president, Dr. Randolph Winslow; secretary, Dr. John Ruhräh, and treasurer, Dr. W. S. Gardner.

Health Bureaus.—Announcement was made by Dr. Nathan Gorter at the thirteenth annual banquet of the employees of the Baltimore Health Department, December 30, that the health department would be organized into bureaus, that it may be more effective in preserving the public health. The first bureau was created Jauary 1, is known as the Bureau of Food and Dairy Inspection, and is in charge of Dr. Frederick C. Blanck, the department chemist. The other bureaus are to be those of infectious diseases, plumbing and sanitation, vital statistics and laboratories. Details of these bureaus will not be complete until the health department is installed in its new quarters in the old Polytechnic Building, which is expected to be ready some time in April.

Appointments at Hopkins Hospital.—Announcement was recently made by Dr. Rupert Norton, assistant superintendent of the Johns Hopkins Hospital, that two young physicians, sons of professors of medicine in this country and Europe, had been appointed assistant resident physicians at the hospital. They are Dr. Carl von Noorden, Jr., son of the head of the department of medicine at the University of Vienna, and a native of Frankfort, Germany, who will assist Dr. Lewellys F. Barker, and Dr. George Minot, son of Dr. Charles S. Minot, professor of anatomy at the Harvard Medical School, who has arrived to assist Dr. William H. S. Thayer. The arrival of Dr. von Noorden marks a new system whereby European physicians will be attached to the staff of Hopkins and in turn young physicians of Hopkins will be sent abroad to work at the Universities of Vienna and Berlin and various English and French hospitals.

Personal.—Dr. Samuel T. Nicholson, Jr., superintendent of Sydenham Hospital, Baltimore, has tendered his resignation to take effect March 1.——Dr. David I. Macht, Baltimore, has been reelected president of the Jewish Academicians of Baltimore.——Dr. John D. Cronmiller, Laurel, who has been under treatment at the Maryland University Hospital, Baltimore, has returned home much improved.——Dr. Gerard H. Lebret, Baltimore, has resigned as chief of the resident physicians of St. Luke's Hospital to accept a similar position in Stamford, Conn.——In the case of Mrs. Bertha Stevenson against Dr. Guy L. Hunner, Baltimore, in which negligence after surgical operation was charged, in which a verdict for $1,000 was rendered by the superior court, the court of appeals, in a decision delivered December 3, reversed the judgment of the lower court.——A fire in the office of Dr. Myer W. Aaronson, Baltimore, December 14, caused damages estimated at more than $1,000.——Dr. Charles Bagley, Jr., formerly of Baltimore, who has for the past year been first assistant to Dr. Harvey Cushing, chief surgeon of the Peter Bent Brigham Hospital at Boston, Mass., has returned to Baltimore.

MASSACHUSETTS

Personal.—Dr. Edward O. Otis, senior physician of the tuberculosis department of the Boston Dispensary, has retired from active service and become consulting surgeon.——Dr. Robert W. Lovett has been appointed consulting physician of the orthopedic physicians' department of the dispensary.——Dr. A. Warren Stearns has been appointed physician-in-charge of the department of mental diseases.——Dr. James J. Scannell has been appointed to be director of the bacteriologic department of the Boston Health Department.——Dr. John A. Seconi, Dorchester, has been appointed inspector of contagious diseases of the Boston Board of Health.——Dr. William A. Brooks, surgeon-in-chief at St. Elizabeth's Hospital, has retired.——Dr. Robert D. Hildreth, Westfield, has been appointed assistant medical examiner of Hampden County; Dr. George A. Stickney, Beverly, medical examiner for Essex, and Dr. Edward S. Smith, Westfield, medical examiner for the Western Hampden district.——Dr. William J. Gallivan has been appointed chief of the division of child hygiene of the Boston Board of Health.——Dr. Wallace E. Brown has been reelected mayor of North Adams.

MICHIGAN

Hospital Non-Sectarian.—Grace Hospital, Detroit, has removed sectarian distinctions, and now admits any reputable, competent physician to its staff, regardless of the particular school of medicine with which he may be affiliated.

University Hospital Wants Leper.—Dr. A. S. Warthin, Ann Arbor, has suggested to the State Board of Health that Jake Goldstein, the leper of Benton Harbor, be sent to the University Hospital, Ann Arbor, for isolation and treatment.

Personal.—Henry F. Vaughan has been appointed to succeed William G. Williamson as sanitary engineer of the Detroit Board of Health.——Dr. John L. Burkhart, Big Rapids, has been appointed secretary of the State Board of Health, succeeding Dr. Robert L. Dixon, Lansing, who has been appointed secretary of the State Board of Epilepsy.

Federal Investigation.—The federal investigation of diphtheria and other communicable diseases in Detroit began December 17. Surgeon Joseph Goldberger, U. S. P. H. S., is in charge of the investigation, assisted by a staff of six experts. The Detroit data will be available for use in combating epidemics elsewhere in the United States.

Hospitals to Amalgamate.—An agreement was reached by the trustees of Harper Hospital, Detroit, and those of the Detroit General Hospital looking toward amalgamation of the two institutions. At a joint meeting of the committee, December 15, a resolution was passed declaring it desirable for the two institutions to unite their physical, professional and financial interests under one general organization which is to be known as the Harper General Hospital.

New Officers.—St. Clair County Medical Society at Port Huron: president, Dr. Henri Cote; secretary, Dr. Richard K. Wheeler, both of Port Huron.——Lenawee County Medical Society at Adrian, December 23: president, Dr. Isaac L. Spaulding, Hudson; secretary-treasurer, Dr. Frank A. Howland, Adrian.——Battle Creek Anti-Tuberculosis Association, December 16: president, W. J. Smith; vice-president, Dr. Albert J. Read; secretary, Miss Mary Anderson.——Gratiot County Medical Society at Alma: president, Dr. Isaac N. Monfort, Ithaca; secretary-treasurer, Dr. Ernest M. H. Heifield, Riverdale.——Ontonagon County Medical Society at Ontonagon: president, Dr. Frank W. McHugh; secretary-treasurer, Dr. John S. Nitterauer, both of Ontonagon.——Emmet County Medical Society at Petoskey: president, Dr. Levi W. Gardner, Harbor Springs.——Kent County Medical Society at Grand Rapids, December 10: president, Dr. Alexander M. Campbell; secretary-treasurer, Dr. Jacob J. Fabian, both of Grand Rapids.——Kalamazoo Academy of Medicine, thirteenth annual meeting, December 9: president, Dr. James E. Maxwell, Decatur; secretary, Dr. Clarke B. Fulkerson, Kalamazoo.

MINNESOTA

Medical Examiners Reappointed.—Announcement is made of the reappointment of Drs. Annah Hurd, Minneapolis, Frank R. Wieser, Windom, and Robert D. Matchan, Minneapolis, as members of the State Board of Medical Examiners for three years.

Sanatorium for Hennepin County.—A committee has been appointed by the Board of Commissioners of Hennepin County to select a site for the erection of a county hospital for tuberculosis, to cost $100,000, one-half of which is to be appropriated from the state funds, the remainder to be raised by the county.

State Board May Keep Fees.—In the suit of the state of Minnesota against Dr. W. S. Fullerton, secretary of the State Board of Medical Examiners, regarding approximately $18,000 fees used by the board, and regarded by the attorney-general to belong to the state, the supreme court, on December 26, decided that the State Board is entitled to fees so collected.

St. Paul, Not Minneapolis.—Dr. Howard Lankester, commissioner of health for St. Paul, asks that the statement made in THE JOURNAL of December 13, regarding the first use of the law concerning the removal of tuberculosis patients from homes to hospitals, be corrected, as it was the Health Department of the city of St. Paul, on December 25, which first called into use the law there cited.

New Officers.—Blue Earth County Medical Society at Mankato, December 29: president, Dr. Gerhard A. Dahl; secretary, Dr. Roy N. Andrews, both of Mankato. A resolution was unanimously adopted concerning the contagion, prevention and treatment of tuberculosis and urging the citizens and commissioners of Blue Earth County to erect a sanatorium at the earliest possible date.

Personal.—Dr. William L. Freeman, Foley, is seriously ill at his home with pneumonia.——Dr. Margaret Fleming has resigned as a member of the St. Peters' Hospital staff, to take a similar position at Independence, Iowa.——Dr. John C. Whitacre, St. Paul, sustained several injuries as a result of the overturning of his motor car, December 20.——Dr. Walter Courtney, for twenty-five years chief surgeon of the Northern Pacific System, was guest of honor at a banquet given at Brainerd, December 26, at which appreciative resolutions were adopted and a silver loving-cup was presented.——Dr. David E. Seashore has been elected a member of the Duluth Board of Education to fill the position which Dr. S. H. Boyer resigned.

NEW YORK

Personal.—Dr. William F. Campbell, Brooklyn, president of the Medical Society of the State of New York, was the guest of honor at a banquet given by Dr. Frederick C. Merritt at Sayville, December 30.——Dr. Stephen A. Mayhew, Utica, has been appointed coroner of Oneida County.

Check Child Insurance.—At a recent conference the state department has succeeded in inducing the industrial life insurance companies to eliminate excessive insurance on the lives of children. Although the state law and the police contracts forbid excess insurance, there has been a great deal of this business done.

Alien Insane a State Grievance.—Governor Glynn's message points out the injustice of shouldering the care and maintenance of 9,000 alien insane on New York simply because it is the nation's receiving ground for foreign immigration. He urges that some action be taken in this matter to relieve the state of this burden.

Bill to Stop Mercury Sales.—A bill was introduced into the Senate by Senator Blauvelt on January 6, inserting in the penal law a new section prohibiting the sale of bichlorid of mercury except on the written prescription of a physician. The bill also requires that the drug shall be sold only in the form of green cubes and prohibits the refilling of prescriptions.

The Work against Tuberculosis.—The supervisors of Westchester County have voted to purchase a 225-acre site at North Castle, and to construct a sanatorium, which is to cost $200,000.——The contract for the construction of the Onondaga County Tuberculosis Sanatorium was awarded by the board of supervisors of Syracuse, December 31, for $123,021.——The supervisors of Broome County have voted to take over the sanatorium property of the Binghamton City Hospital, and will build an institution to be used as a tuberculosis sanatorium.

New York City

Harvey Society Lecture.—The seventh Harvey Society lecture will be given January 24 by Prof. Sven G. Hedin, University of Upsala, who will make an address on "Colloidal Reactions and Their Relations to Biology."

Spitzka Dead.—Dr. Edward Charles Spitzka, the noted alienist and specialist on nervous and mental diseases, died at his home in New York City, January 13, from cerebral hemorrhage. An obituary notice will appear in THE JOURNAL, January 24.

Neurologists Elect.—The New York Neurological Society has elected the following officers: president, Dr. Smith Ely Jelliffe; first vice-president, Dr. Edwin G. Zabriskie; corresponding secretary, Dr. J. Ramsey Hunt, and recording secretary, Dr. Charles E. Atwood.

Typhus Ship Comes to Port.—The Fabre liner *Roma* from Marseilles and Italian ports has arrived in this port from Providence, having been ordered here by Surgeon-General Blue, as Providence has not the facilities for caring for typhus and quarantining so large a number of passengers. The 258 steerage passengers from this vessel have been quarantined at Hoffman's Island and the twenty-three who occupied the same section with the typhus patient have been placed in a special isolation ward.

A Good Year for Babies.—The Bureau of Child Hygiene of the Department of Health reports that the total number of deaths of children under 1 year of age in the city last year was 13,772. In 1912, 14,260 died. The infant death-rate in 1912 was 102 per 1,000 births and last year only 98.7. Allowing for the increase in population this means a saving of 1,069 lives. Dr. S. Josephine Baker, chief of the Bureau of Child Hygiene, expressed the opinion that organized parental education carried on by the infant welfare organizations has been responsible in a large measure for this satisfactory showing.

Transfer of Pasteur Clinics.—The administration of the Pasteur treatment for rabies has until Jan. 1, 1914, been carried on at the Research Laboratory and the Brooklyn Borough office. On January 1, this work was transferred to the Bureau of Infectious Diseases, and a daily clinic from 1 to 4 p. m., in Room 802 on the eighth floor of the Department Headquarters, 149 Centre Street, was established. On Sundays and holidays, patients from Manhattan are referred to the Brooklyn clinic, at the Brooklyn Borough office, Flatbush Avenue and Willoughby Street, between the hours of 10 and 12 a. m. A clinic will also be established at the Bronx Borough office in the near future. For the present, cases from the Borough of Queens are referred to the Brooklyn clinic, and cases from the Borough of Richmond, to the Manhattan clinic for treatment.

Physical Examination of Children in Institutions.—In the appropriation for the Division of Child Hygiene for 1913 was included an item of $10,000 to be used for extending the work of the division to the institutions of the city caring for children, thus giving them the same system of physical examination as is provided for the children in the public and parochial schools. There are sixty-three such institutions in New York City and from March 29 to October 18, 14,697 children were examined. Of these 6,486 were found to be normal, while 8,211 were found to be suffering from one or more physical defects. The total number of defects found was 10,884. In general the percentage of defects was about the same as that noted in the children in the public schools, an exception being noted in the case of defective teeth. This defect was found among the institution children in only 38 per cent. of the cases, while among the children in the public and parochial schools 49 per cent. were found to have defective teeth. This was undoubtedly due to the greater attention paid to this subject by the institutions. In October the children were reexamined to ascertain if the treatment provided had had the desired result. It was found at that time that 2,730, or 44 per cent, of the children were entirely cured; 1,868, or 30 per cent., were improved, while 1,593, or 25 per cent., remained unimproved. The percentage cured was remarkable as indicating what could be done even in a brief space of time when it was possible to apply prompt and direct attention to the needs of the children.

NORTH DAKOTA

Tablet Unveiled.—A bronze tablet, presented by the citizens of Valley City in recognition of the success of Dr. Ludwig S. Platou in establishing a pure water-supply for that city, was unveiled January 1 with appropriate ceremonies.

New Hospital for Bismarck.—The sisters of the order of St. Benedict have selected a building site in Bismarck on which to erect a new hospital to be known as St. Alexius' Hospital; the building will cost about $100,000, will consist of a central building and two wings, of brick construction, fireproof throughout, and will accommodate one hundred patients.

New Officers.—Sixth District Medical Society at Bismarck, December 16: president, Dr. Paul F. Rice, Cannon Ball; secretary-treasurer, Dr. William B. Foster, Mandan.——North Dakota Anti-Tuberculosis Association: president, Dr. James Grassick, Grand Forks; secretary, Dr. Fannie Dunn Quain, Bismarck.——Tri-County Medical Society at New Rockford: secretary, Dr. J. Roy Mackenzie, New Rockford.

Personal.—Dr. Julius A. Johnson has closed his hospital at Bottineau and has presented much of the equipment to St. Andrew's Hospital, which recently opened in the city.——In the case of Carrie Lee against Dr. William P. Baldwin, Casselton, in which malpractice was charged, the jury decided in favor of Dr. Baldwin.——Dr. William C. Nichols has been appointed physician of the North Dakota Agricultural College.

PENNSYLVANIA

Refused Charters to Chiropractors.—On January 5 Justice Potter handed down an opinion in the supreme court affirming the order of the common pleas court of Pittsburgh, which denies a charter to chiropractors.

Personal.—Dr. James K. Weaver, Norristown, surgeon-general of the state, was installed as surgeon-general of the Grand Army of the Republic, January 5.——Dr. J. W. McClellan has resigned as member of the staff of the Moses Taylor Hospital, Scranton.——Dr. John G. L. Myers has been elected mayor of Osceola Mills.

Springfield Water Infected.—At a conference held at the Merion Cricket Club, January 9, the officials of the Springfield Water Co. were attacked by the officers of the Board of Health of Lower Merion Township for the presence of typhoid fever bacilli in the water. Several officials were sent by Dr. Samuel Dixon to represent the state and a further conference will be held in Ardmore when Dr. Dixon will be present. Dr. David Wilbur Horn of Bryn Mawr, chemist for the Lower Merion Board of Health, and Dr. B. K. Wilbur, its president, led the attack.

License for Midwives.—The Bureau of Medical Education and Licensure of the State of Pennsylvania, has taken steps to enforce the act passed by the last legislature, which provides for the better protection of the lives and health of newborn children, by regulating the midwifery as performed by midwives in this state. It is the intention of the bureau to follow up every midwife in the community and see that she obtains a state license. All women licensed will be frequently visited, their work inspected and the results of their work carefully noted.

Grade Crossing Deaths.—After the report of Investigator Dohoney on grade crossings in the state, the first of its kind ever made in this state, had been read, the Public Service Commission instructed the investigator to prepare regulations for the safety of travelers over these crossings; 114 steam railroads cross public roads at grade in 11,763 instances and of these 10,144 are unprotected. The necessity for such supervision is emphasized by the following statement of grade crossing accidents in six years:

Year	Killed	Injured
1908	72	299
1909	72	356
1910	86	222
1911	84	252
1912	106	306
1913	111	283
Total	531	1,718

Action on Death of S. Weir Mitchell.—A special meeting of the College of Physicians was called January 6, to take action on the death of Dr. S. Weir Mitchell.——At a meeting of the Philadelphia Neurological Society held in the hall of the College of Physicians Jan. 5, 1914, a committee was appointed consisting of Dr. Charles K. Mills, Dr. F. X. Dercum and Dr. James Hendrie Lloyd to prepare a minute regarding the death of Dr. S. Weir Mitchell, first president of the society. The resolutions express sorrow at the death of Dr. Mitchell, the stimulation of his presence and example and the sense of loss of a valuable adviser, helper and friend.

Remarks relating to Dr. Mitchell's distinguished career and especially his connection with neurology in Philadelphia and in the country at large were made by the president, Dr. George W. Price, and by Drs. Mills, Dercum and Lloyd.

Philadelphia

Personal.—Dr. M. Frazer Percival has succeeded Dr. Charles Lester Leonard, deceased, as roentgenologist of the Philadelphia Polyclinic.——Edward C. Kirk, dean of the Dental School, University of Pennsylvania, has just been elected an honorary member of the National Dental Society of Finland.

Memorial Meeting for Dr. Musson.—A memorial meeting for Dr. Emma E. Musson, clinical professor in otology in the Woman's Medical College of Pennsylvania, who died December 28, was held at the college January 5, by the Alumni Association. Dr. Eleanor C. Jones, president of the association, presided, and the speakers included Dr. Clara Marshall, dean of the faculty, Mrs. Wilfred Lewis, president of the board of corporators, and Drs. E. R. Bundy, Frances Studert and A. H. Goodwin.

Students at Drexel Vaccinated.—On January 9, thirty girls and twenty boys of the Drexel Institute were vaccinated as a result of a small-pox scare which developed in the institution January 8. A student in the Department of Commerce and Finance, who had returned to school after his mother had been stricken with small-pox, was taken to the Municipal Hospital and isolated as a precaution. The house where he was rooming and the boarding house were placed under quarantine until all had been vaccinated.

New Officers.—Northeastern Branch of the Philadelphia County Medical Society: vice-president, Dr. Horatio Pilkington; chairman, Dr. George Hanna; clerk, Francis F. Borzell. ——Philadelphia Pediatric Society: president, Dr. William N. Bradley; secretary-recorder, Dr. Maurice Ostheimer.——College of Physicians of Philadelphia, January 6: president, Dr. James C. Wilson; secretary, Dr. Thomas P. Neilson.——Obstetrical Society of Philadelphia, January 2: president, Dr. George Eraty Shoemaker; secretary, Dr. Edward Schumann.

SOUTH CAROLINA

Doctors' Building for Columbia.—A stock company has been organized in Columbia to erect a building to cost about $150,000, for the especial use of physicians and dentists.

Medical Library for Society.—The municipal council of Columbia has given a room on the second floor of the City Hall to be used as a library for the Greenville County Medical Society.

Public Health Work of State Association.—At a called meeting of the Medical Association of the State of South Carolina held at Columbia, December 16, the association pledged itself to vote for the bill now pending regarding medical inspection in the schools of the state; to work for a state hospital for the insane; to urge the legislature to uphold the appropriation asked for by the State Board of Health; to defend the law requiring the collection of vital statistics in the state, and to ask that the State Board of Health be asked to make an appropriation for a state hospital school for tuberculosis patients in the incipient stages, and for the study of pellagra, and also a hospital for the treatment of that disease.

New Officers.—Laurens County Medical Society at Laurens, December 22: president, Dr. George J. Klugh, Cross Hill; secretary, Dr. Jefferson D. Austin, Clinton.——Columbia Medical Society, December 16: president, Dr. F. Asbury Coward; secretary-treasurer, Dr. Edyth Wellbourne.——Dorchester County Medical Society at St. George, December 8: president, Dr. F. Julian Carroll, Summerville; secretary, Dr. John B. Johnston, St. George.——Saluda County Medical Society at Saluda, December 8: president, Dr. Jonathan D. Waters; secretary-treasurer, Dr. Clough H. Blake, both of Saluda.——Greenwood County Medical Association at Greenwood, December 4: president, Dr. Joseph S. Fauche, Ninety-Six; secretary-treasurer, Dr. John F. Simmons, Greenwood.——Greenville County Medical Society, December 2: president, Dr. Charles O. Bates; secretary, Dr. Samuel G. Glover (reelected), both of Greenville.——Pee Dee Medical Society at Florence, November 24: president, Dr. Julius Alexander Faison, Bennettsville; secretary-treasurer, Dr. Joseph Coke Lawson, Darlington.

SOUTH DAKOTA

New Officers.—Yankton (Eighth District) Medical Society at Yankton, December 15: president, Dr. Charles M. Keeling, Springfield; secretary-treasurer, Dr. James Roane (reelected).——Watertown District Medical Society at Watertown, December 9: president, Dr. Hervey A. Tarbell; secretary, Dr. Stanley B. Dickinson, both of Watertown.——Black Hills Medical Society at Lead: president, Dr. Felix E. Ashcroft, Deadwood; secretary-treasurer, Dr. Frederick W. Minty, Rapid City.

TENNESSEE

Hospital Property Sold.—The property of the Galloway Hospital at Sixteenth Avenue and Division Street, Nashville, has been sold to Drs. Robert O. Tucker and H. R. Sharber, who will build a sanatorium on the site.

Personal.—Dr. John C. Bell has succeeded Dr. Max Goltman, resigned, as superintendent of the Memphis Health Department.——Dr. Cummings Harris has succeeded Dr. Bell as secretary of the Health Department and Dr. Newman Taylor has been appointed City Health Officer.——Dr. H. B. Coyle has been reelected director in the Southern Tennessee Sanitarium Association.——Dr. Vincent A. Biggs, Memphis, has been appointed a member of the State Board of Health, vice Dr. Louis Leroy.——Dr. Z. D. Massey, Sevierville, who was recently operated on for appendicitis, has recovered and has resumed his work as physician at the state prison.——In the case of Dr. L. A. Yarbrough, Covington, against the Second Bank and Trust Company, Memphis, in which $50,000 damages was asked, and it is claimed that the complainant actually suffered a loss of $19,000, a verdict of $4,000 was rendered by the jury, December 1.——Dr. A. S. Newton Dobson, Limestone, is reported to be seriously ill.——At the semi-annual meeting of the State Board of Health held at Nashville recently, Dr. William Litterer was reelected State Bacteriologist.

New Officers.—Hamblen County Medical Society at Morristown, December 22: president, Dr. S. M. Ryburn; secretary-treasurer, Dr. C. F. Carroll, Jr.——Roane County Medical Society at Harriman, December 19: president, Dr. Eugene S. Philips, Rockwood; secretary, Dr. William W. Hill, Harriman.——Memphis and Shelby County Medical Society at Memphis, December 16: president, Dr. Alfred B. DeLoach; secretary, Dr. James L. Andrews.——Wilson County Medical Society at Lebanon, December 12: president, Dr. Jerry James McFarland; secretary, Dr. Byrd S. Rhea.——Tipton County Medical Society, Covington, December 11: president, Dr. T. B. Gassaway, Tabernacle; secretary-treasurer, Dr. L. J. Lindsay, Covington (reelected).——Chattanooga Medical Society, December 5: president Dr. Walter G. Bogart; secretary-treasurer, Dr. G. Victor Williams.——Jefferson County Medical Society at Jefferson City, December 2: president, Dr. B. F. Brown; secretary, Dr. Buford M. Tittsworth, both of Jefferson City.——Maury County Medical Society at Columbia, December 12: president, Dr. Otey James Porter; secretary-treasurer, Dr. P. D. Biddle, Columbia.——Middle-Tennessee Medical Society at Columbia: president, Dr. George E. Hatcher; secretary-treasurer, Dr. Roy W. Billington, Nashville.

UTAH

New Officers.—Weber County Medical Society at Ogden, December 18: president, Dr. Amasa S. Condon; secretary-treasurer, Dr. Carlyle K. MacMurdy, both of Ogden.——Salt Lake County Medical Society at Salt Lake City, December 18: president, Dr. Ernest D. Hammond; secretary, Dr. Robert W. Ashley, both of Salt Lake City.

Personal.—Dr. C. L. Shields has succeeded Dr. Edwin F. Chamberlain as assistant county physician of Salt Lake City.——Dr. David B. Anderson, Salt Lake City, has been appointed a member of the house staff of Mount Sinai Hospital, New York City.——Dr. William T. Cannon, Salt Lake City, fell December 21, dislocating his elbow.——Dr. Jacob D. Harding, Brigham City, has sailed for Europe.

WISCONSIN

Emergency Cases Supplied.—In compliance with the recent law, the railways of the state are supplying first-aid-to-the-injured cases to all trains in the state; in freight trains these cases are carried in the caboose, in passenger trains in the baggage car.

Hospital News.—The first floor of the Beloit Hospital has been converted into offices for the members of the staff of the institution, laboratories, Roentgen ray rooms, etc.; Drs. A. C. Helm and Paul A. Fox are the first physicians to occupy offices in the building.

Personal.—Dr. George R. Ernst has succeeded Dr. Daniel B. Riley as chief of the Blue Mounds Sanatorium.——Dr. Wilhelm F. Becker has been elected president and Dr. Oscar Lotz secretary of the visiting staff of Mercy Hospital, Milwaukee.——Dr. Arthur C. Helm, Beloit, has moved from his offices in the Parker Block, which he has occupied for more than thirty years, to the Beloit Hospital.——Dr. Andrew Uren, physician of the Montreal mine, has been granted leave of absence and sailed with his wife for Europe, January 15.——Lieut. A. W. Geyer, second assistant surgeon of the National Soldiers' Home, Milwaukee, has been transferred as first assistant to the Soldiers' Home at Hampton, Va.

Hospital Notes.—Riverview, the Outagamie County tuberculosis sanatorium, just outside the city limits of Kaukauna, has been accepted by the county and by the state board of control, and is ready to receive patients. There are thirty applications on file. The sanatorium has sixteen individual rooms, and two wards accommodating three patients each, and with the sun porches can receive thirty-four patients.——The city council of Rhinelander has arranged for an isolation hospital to be located near St. Mary's Hospital.——Eau Claire County Tuberculosis Sanatorium opened December 18 with twenty patients. The sanatorium has been completed at a cost of $16,000, the site having been donated by the Eau Claire Tuberculosis Society.

New Officers.—Dunn County Medical Society at Menominee, December 28: president, Dr. Lauritz A. Larsen, Colfax; secretary, Dr. George A. Barker, Menominee.——Rock County Medical Society at Janesville, December 30: president, Dr. John W. Keithley, Beloit; secretary-treasurer, Dr. Fred E. Sutherland, Janesville.——Eau Claire County Medical Society at Eau Claire, December 29: president, Dr. F. S. Cook; secretary-treasurer, Dr. Roy Ernest Mitchell, both of Eau Claire.——Sheboygan County Medical Society at Sheboygan, December 19: president, Dr. John A. Junck; secretary-treasurer, Dr. George Edmund Knauf, both of Sheboygan.——Ashland County Medical Society at Ashland, December 16: president, Dr. William T. Rinehart, Ashland; secretary, Dr. George W. Harrison (both reelected), both of Ashland.——Grant and Crawford Counties Medical Society at Fennimore, December 18: president, Dr. S. Wade Doolittle, Fennimore; secretary, Dr. Mina B. Glasier, Bloomington (reelected).——Marathon County Medical Society at Wausau, December 15: president, Dr. Joseph F. Smith; secretary-treasurer, Dr. Richard W. Jones, both of Wausau.——Douglas County Medical Society at Superior, December 14: president, Dr. Charles M. Gould; secretary-treasurer, Dr. William H. Schnell, both of Superior.——Shawano County Medical Society at Shawano, December 10: president, Dr. William J. Ragan (reelected); secretary-treasurer, Dr. Herbert J. Calkins, both of Shawano.

GENERAL

College Reelects Officers.—At the meeting of the Board of Regents of the American College of Surgeons in New York City, January 9, the officers were reelected.

New Pediatric Officers.—At the recent meeting of the New England Pediatric Society, Dr. Charles A. Pratt, New Bedford, Mass., was elected president; Dr. Lester C. Miller, Worcester, Mass., vice-president and Dr. Fritz B. Talbot, Boston, secretary and treasurer.

Chocolate Ration Barred.—The chocolate emergency ration of the Army, long considered a mainstay, has been discontinued on the advice of an officer of the Agricultural Department, as it is "difficult as to its digestibility, and therefore deleterious to the health of the consumer."

Personal.—Dr. Claude C. Pierce, who resigned as superintendent of the Colon, (C. Z.) Hospital, November 26 last, sailed for the United States, January 1, to resume his duties with the service.——Dr. Roger P. Ames, Puerto Cortez, is reported to be ill with a malignant form of fever.

Bequests and Donations.—The following bequests and donations have recently been announced:

National Jewish Hospital for Consumptives, $350,000 for a new building, a donation from the president, Dr. Samuel Grabfelder, Philadelphia.

Jefferson Hospital, Philadelphia, a fund to be known as the Lucy Henderson foundation, with an income of about $3,500, to be used in studying the cure of cancer with especial reference to radium, the gift of Mrs. Lucy Henderson of New Castle, Pa.

German Hospital, Philadelphia, $5,000 to be used as an endowment for free beds as a memorial to his father, by the will of Hermann Hessenbrook.

To establish a training school for nurses in Jerusalem, $10,000, by wealthy Jews of Pittsburgh.

St. Joseph's Hospital, Philadelphia, $5,000; Sisters of St. Francis, St. Mary's Hospital, $5,000; St. Vincent's Hospital and Maternity Home, $3,000, by the will of Annie Grandon.

Third Warning.—More swindlers are at large, collecting money and taking orders from physicians, than ever before. Letters continue to come in from Ohio, Kentucky, Tennessee and Indiana, reporting calls by individuals traveling under the following names: G. A. Wright and W. J. Havelin, representing themselves as agents of the Co-Operative Publishing Co. of New York City, and Walter Thorne and Herbert Masorn, purporting to be our authorized representatives. These parties seem to be making some very attractive offers as premiums on a year's subscription to The Journal—such as Dorland's Medical Dictionary, "Crocker on Skin," "Osler on Diagnosis and Practice," also 29 volumes of Dumas. Our authorized agents carry with them letters of authority, signed by George H. Simmons and bearing the official seal of the American Medical Association. Pay your money *only* to men who can produce the proper credentials and be cautious of extravagant premium offers. Any information that will help us locate the above and stop this unfortunate misrepresentation will be appreciated.

CANADA

New Officers.—Medicine Hat Medical Society, second annual meeting December 15: president, Dr. Oliver Boyd; secretary-treasurer, Dr. W. J. Knight.

Nurses' Needs.—The Victorian Order of Nurses, Montreal, is endeavoring to raise $25,000 for their increased needs in 1914. Seventy-one graduate nurses are now employed in and around Montreal; and during the last twelve months they made 132,483 visits of which 5,514 were night visits.

Vital Statistics.—Toronto's vital statistics for 1913 were as follows: Births, 14,086; as against 11,100 in 1912; deaths, 6,949, as against 6,313 in 1912; marriages, 6,421 as compared with 6,153 in 1912. All the contagious diseases with the exception of measles and typhoid fever showed a lower death-rate. Fifty-two deaths resulted from typhoid, the same as in 1912.

University Offers First-Year Course.—The University of Alberta is offering this session a first-year course in medicine. Ultimately a five-year course will be established. Dr. Daniel G. Revell is in charge of the department of bacteriology. Two professors in medicine will shortly be appointed, one to anatomy and one to physiology. The laboratories for the second year will be set up and equipped during the present year; and then additional appointment will be made from among the local medical men. The legislature has recently passed an anatomy act to provide dissecting material.

Personal.—Dr. Charles F. Martin, Montreal, is leaving for a trip round the world.——Owing to ill health, Dr. Richard W. Garrett, Kingston, has been compelled to relinquish his professional duties and seek rest and recuperation in a sanatorium.——Col. Guy Carlton Jones, M.D., Ottawa, Director-General of the Canadian Medical Services of Canada, delivered an address at the Academy of Medicine, Toronto, January 6, on "Relation of the Medical Profession to the Defense of the Country."——Dr. James H. Hamilton of Revelstoke, B. C., has gone on a visit to Honolulu.——Dr. Walker, surgeon of the expedition which discovered the fate of Sir John Franklin in 1859, has recently arrived in Victoria, B. C., after an absence of fifty years.——Dr. R. B. Boucher, Winnipeg, has returned after several months at the hospitals of Chicago, New York and Montreal.——Dr. Séraphin Boucher is to succeed Dr. Louis Laberge as *chief of the Health Department of Montreal.*

Hospital News.—A separate hospital for small-pox patients has been secured for Brantford, Ont., at a cost of $5,800.——Winnipeg ratepayers have again rejected a by-law to provide $275,000 for the general hospital of that city.——A four-story hospital is being built by the Dominion Government at the Grosse Isle quarantine station.——Rev. Edwin Herbert Grey, M.D., was tendered a reception in Toronto January 2, prior to his departure to assume the superintendency of the Hugh Waddell Memorial Hospital at Canora, Sask. The hospital cost $25,000 and was a gift of Mrs. Hugh Waddell of Peterborough, Ont., and its work will be among immigrants in the Canadian Northwest.——Toronto physicians made a private inspection of the new Private Building of the Toronto General Hospital on invitation of the board of governors, January 6.——The Toronto General Hospital is inaugurating clinics for the physicians of the city, to be held every Thursday afternoon when members of the staff will exhibit cases from the different wards.——Toronto electors refused to sanction a by-law on January 1, to raise $500,000 for two new hospitals to serve the needs of the eastern and western sections of that city.

LONDON LETTER

(From Our Regular Correspondent)

London, Jan. 3, 1914.

The National Insurance Act and the Scarcity of Physicians

In a previous letter to The Journal the effect of the *national insurance act in producing* a scarcity of applicants for administrative medical appointments has been shown. The following further facts may be of interest: The act came into force at the beginning of 1913. Then occurred the annual influenza and bronchitis epidemic, and within a few weeks it became exceedingly difficult for a physician to obtain an assistant or a locum-tenens. Before the employment of unqualified assistants was forbidden, qualified assistants could be engaged for $10.50 a week. Now they obtain as much as $36 and $47. These high figures ruled through the holiday season. Even after this period passed the remuneration of assistants had advanced about 25 per cent. A year ago a physician could be obtained for $600 per annum when living with his principal, who provided food and lodging, or for $900 when living "outdoors." Now the rates are $1,000 and $1,250, respectively. The shipping companies have also had considerable difficulty in obtaining surgeons for their vessels. The rate of remuneration has risen from $50 per month to $75 and even $100, with, in addition, the privilege not hitherto accorded except in a few cases of charging fees from first-class passengers. The royal navy is in a similar predicament as there is a serious deficiency in the number of candidates for surgeoncies. In the country also the deficiency is making itself felt. In the outlying district of the highlands physicians tempted by the new opportunities have in many cases resigned their appointments, and successors cannot be found. At least two parishes in the Orkney and Shetland islands have been without physicians for six months and seem likely to remain so unless the state comes to their assistance with a "grant in aid." The situation is remarkable and unprecedented. In the great industrial centers the physicians are enjoying prosperity previously unknown. Meanwhile, curiously enough, the entries at the great medical schools continue to show a falling off.

Increased Dues in the British Medical Association

During the greater part of its career the activities of the British Medical Association have been mainly scientific. The annual meeting and the communications in the *Journal* dealt almost exclusively with scientific subjects. What was called "medical ethics"—the rules which should regulate the action of one physician toward another—were not neglected but, being a comparatively simple and settled subject, did not give rise to much discussion. In recent years, however, the constantly increasing interference of the state in medical work has produced a profound transformation, and the work of the association has become more and more political. About ten years ago a medical secretary with a clerical staff was appointed to organize the profession and deal with what should be more correctly termed medicopolitical than medico-ethical questions. At this time the association was more than paying its way and had accumulated the substantial surplus of $460,000. Though the new departure of the association was attended by increased membership, the expenditure still more rapidly increased Then came the national insurance act, against which the association fought strenuously The result was a still greater expenditure In 1912 there was a deficit of $80 000, due to the acute stage of the struggle with the government The question of increasing the subscription has therefore been considered at a special meeting of the representative body of the association The Chairman of the council moved that the subscription be increased from the present one of $6 to $10 50 It had been said that a good many members would resign but he thought that many were only waiting for an opportunity or excuse to resign, and the association would be better off without some of them Against the increase one representative pointed out that if the association were to do any good it must include practically every physician and therefore should not run the risk of losing members increased membership was far more important than increased revenue It was also unfair to members who would resign if the subscription were increased, as it would be too late for them to send in their resignations for the forthcoming year Another member gave the results of a postal vote taken in the Marylebone division of London He sent out 665 cards and received 388 answers, about 57 per cent Some of these votes were spoiled In favor of the increased subscription there were 146 against 201 — a majority of 64 against. The question was also asked, "Are you willing to remain a member of the association if your subscription be so increased?" The answers were yes, 175, no, 150, doubtful, 20 The motion to increase the subscription was put to the meeting and carried by 131 votes to 42 A number of proposals bearing on the increased subscription was then discussed It was proposed that in order to encourage newly qualified physicians to join the association they should be exempted from the increase for five years In the end a motion was passed instructing the council to draft a by law for submission to the divisions of the association that special consideration should be given to newly registered physicians An Irish representative moved that the increased subscription be increased only in those areas in which medical benefit under the insurance act was in force Ireland wanted to be left out, first, because there was no medical benefit there, and secondly because there was already an Irish Medical Association the dues in which were $5 a year, which was essential for their protection Another Irish member spoke to the contrary and on vote the motion was lost A similar proposal exempting the channel islands, for the same reason, was also lost It was also proposed to exempt naval and military medical officers who spent the greater part of their time abroad, as it had already been decided that the increased dues were not to apply to colonial members of the association (It may be pointed out that in some colonies, for example Australia and New Zealand, the members of the association already pay increased dues of $10 50, half of which go to the funds of the association in London and the other half for the local branch which supplies them with a local journal) The motion to exempt military and naval medical officers was lost.

PROPOSED FIGHTING FUND

A proposal was then brought forward to establish a special fund under the following conditions Membership to be voluntary on the basis of an annual subscription of $21 Of this sum it was proposed to allocate $7 50 per member for local use and $13 50 for central use It was also proposed to appoint seven district medical organizers at $3,000 per annum to preach the gospel of organization The fund was also to provide insurance for medical defense against adverse verdicts in accidents and sickness, and to provide an endowment policy or pension at 65 years of age The proposal was put to the vote and 111 representatives voted for it and 66 against As the requisite two thirds majority was not obtained, the proposal was lost A long discussion then took place with regard to a campaign in favor of such a fund The object of the fund would be to recoup members whose financial position might not be sufficient to enable them to make a stand with the rest of the profession One member did not believe it would ever be possible to prevent a small minority of the profession taking underpaid work Could the men who went on the panel against the declaration of the association be depended on in making a stand in the future? He thought not and that therefore the special fund would be a fiasco It was decided that the council be instructed to consider the whole question and submit it to the divisions in order that it might come before the next annual representative meeting

Measures Against Venereal Diseases in Australia

The appointment of a royal commission on venereal diseases following the recommendation made by the recent International Medical Congress has been reported in a previous letter to The Journal Evidence has been given on the measures adopted by the state in Australia Dr Burnett Ham, who from 1900 until this year was head of the health department in the state of Victoria, described the measures recently taken As a first step syphilis was made a compulsorily notifiable disease in the Melbourne area, though notification was not enforced by penalties and no names were given Physicians were asked to send specimens of the blood for the Wassermann test In the course of a year 5 000 notifications were made and an equal number of blood specimens submitted, 3,500 notifications were made by private physicians, 900 by the Melbourne Hospital and 1,100 by the Eye and Ear Hospital Of the 5,500 Wassermann tests, 1,900 were positive and 400 partial It was calculated that this corresponded to a number of cases equivalent to 0 5 per cent of the population, a figure much lower than had been anticipated At the Eye and Ear Hospital, out of 5 500 patients presenting themselves during a certain period, 75, or 13 6 per cent, gave a partial or positive reaction Statistics furnished by the Women's Hospital showed that 50 per cent of the major operations were performed for conditions due to gonorrhea The government provided free beds for the treatment of these diseases with modern equipment At first there was some difficulty in filling them, but when it became known that the patients would not be dealt with differently from those in other wards a good demand for the beds arose Dr Ham thought that the experiments conducted at Melbourne had led to a greater interest in the subject and to securing early treatment and diagnosis A health bill was at present before the Victoria legislature which contained provision for adequate and gratuitous treatment and for making the transmission knowingly of venereal diseases a penal offense

PARIS LETTER

(From Our Regular Correspondent)

Paris, Jan 2, 1914

Localization in the Brain

In recent years, the works of Pierre Marie have shaken the theory of aphasia, which used to be generally considered as connected with the destruction of the third left frontal convolution. Dr R Robinson has just communicated to the Académie des Sciences a case probably unique of its kind which shows the lack of solidity of the theory of cerebral localizations A hemophiliac, aged 62, was wounded in the occiput Slight bleeding followed The accident had been forgotten for a long time when the patient began to have trouble with his sight An oculist found marked stasis of the left papilla The patient's intelligence and memory were slightly affected The patient had no pain His speech was somewhat defective, but that might have been attributed to missing teeth Hearing, taste and touch were almost normal The sight decreased more and more Finally, about a year after the onset of the trouble, he died from an attack of jacksonian epilepsy When the skull was opened, the brain was found much enlarged It weighed about 1,800 gm (nearly 5 pounds) and dilated veins covered the surface on a pale rose colored background An incision in the bulging part released extraordinarily fetid pus When this pus had been evacuated, there remained only a thin shell of cerebral substance The two frontal lobes, the parietals, the temporals, the occipitals, etc, were in great part decayed, notwithstanding which the patient had lived for almost a year without appreciable pathologic phenomena Van Gehuchten recently published reports of one case in which a larger tumor flattened out two frontal lobes in a young man of 27, and another of an immense abscess, which had destroyed the whole left lobe, neither of which gave rise to any symptoms of serious brain lesions

New Medical Review

There are few medical periodicals in France devoted to original research Hence many interesting researches are published under the form of brief notes in the proceedings of scientific societies and consequently without the data necessary for proof This habit of publishing brief notes tends to favor the premature publication of incomplete researches and of hasty conclusions Therefore, a group of physicians of the hospitals and *agrégés* of the Faculté de médecine de Paris have founded a new organ, the *Annales de médecine*, which will appear each month, each number containing about ninety pages This review, published by Masson et Cie, will contain only original papers and a critical review, but no abstracts of current periodicals and no society proceedings

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec. 27, 1913.

Personal

Professor Gaffky, who has been connected with the Robert Koch Foundation for the Campaign against Tuberculosis since its origin and who now loses his membership in consequence of his resignation from the office, has been chosen to honorary membership in the institution. Heretofore, the only honorary member has been Carnegie, who was elected because of his donation of $125,000 (500,000 marks).

The Insurance Crisis

The negotiations with the insurance societies to which attention was called in the previous letter, which were conducted under the auspices of the government at the instigation of the representatives of the German medical faculties, were concluded on the twenty-third with a favorable settlement. Inasmuch as this involved a compromise for which both parties must usually make sacrifices, a large number of the demands of the German medical profession were not acceded to, and it goes without saying that many physicians have regarded this settlement with mixed feelings. Still I think that the advisory board of the Leipsic League, which will meet at Leipsic at the call of the board of directors, December 28, to make the final decision regarding this matter, will sanction the agreement. For even if the German physicians should stand by one another with complete unanimity and prepare themselves for a long struggle, still it is not to be denied that the material losses which they would suffer on account of the struggle would be very considerable. As soon as a conclusion is reached with regard to this extremely important matter I will let you know the result and the terms of the compact.

Exchange of Surgical Assistants between America and Germany

The long-promised arrangement for an exchange of assistants between the surgical clinics of Johns Hopkins University and of the University of Breslau has been accomplished at last. Privat-Docent Dr. Felix Landois, the assistant of Professor Küttner, goes from Breslau to Baltimore for six months to fill a place as assistant which has been provided for him, while the first assistant of Professor Halsted, Dr. George Heuer, goes to Breslau, to serve in Landois' place.

Comparison of Health Conditions Among Male and Female Teachers at Berlin

Statistics show that in Berlin, notwithstanding the less stringent requirements which are made of the female teachers with reference to the number of hours of work, the feminine teaching force fails much sooner and more frequently than is the case with the men. The result of this condition, aside from other inconveniences, is a greater overwork of the men, who to a certain extent (as is also the case vice versa) have to act as substitutes for the women teachers who are sick. Among 3,579 men teachers in the public schools, only 791 lost time on account of sickness in 1912; nearly as many of the women teachers, namely, 714, were also excused from duty on account of sickness, although their total number was only 1,704. Of the 384 female special teachers, 193 were excused for this cause.

The picture becomes still more unfavorable for the vitality of the women when it is learned how long the sickness lasted. The men teachers were excused on this account for 30,727 days, while the corresponding figure for only half as many women teachers was 35,629 days.

Berlin makes quite extraordinary demands not only on the women but also on the men. Here and there the work is made harder by the agitation which is made by the social democrats against the schools and their teachers. In such cases the maintenance of discipline presents great difficulties; but, in spite of all, the frequent breaking down of women teachers in the Berlin public schools is a serious phenomenon which should concern not only the physicians, but should not remain unnoticed by the leaders of the woman movement. After affections of the organs of respiration, which are in general very frequent (among men 204 and among women 178), nervous diseases rank next. Among the absences for sickness of the 3,579 men teachers, there were 178 on account of nervous affections, while among the 1,704 women teachers, 191 were excused on account of nervous affections.

Marriages

Louis Hopewell Bauer, M.D., M. R. C., U. S. A., Washington, D. C., to Miss Helena Meredith of Jamaica Plain, Mass., December 27.

David Benjamin Tuhloski, M.D., to Miss Mildred B. Chase, both of Brocton, Mass., at Erie, Pa., December 29.

Verne H. Bantleon, M.D., Jr., Kansas City, Kan., to Miss Alma Bell Davis of Hiawatha, Kan., December 30.

Robert Hervey Lafferty, M.D., to Miss Edith Katherine Fry, both of Charlotte, N. C., December 21.

Eugene W. Caldwell, M.D., New York City, to Miss Nellie Perkins of Burlington, Wis., December 25.

Charles Day Shuart, M.D., Brandon, Wis., to Miss Ethel Halsey of Oakfield, Wis., January 1.

Henry P. Bevis, M.D., Arcadia, Fla., to Miss Florence Henshew of Oakland, Fla., December 24.

Roscoe Patrick Cheney, M.D., to Miss Clara Lucile Walsh of Clinton, Iowa, November 27.

John C. Bump, M.D., to Mrs. Leverne Crocker, both of Spokane, Wash., December 28.

Herman L. Wichman, M.D., to Miss Pearl Wilson MacCoy, both of St. Louis, January 3.

Moyer S. Fleisher, M.D., to Miss Adele Levis, both of St. Louis, recently.

Deaths

David W. Steiner, M.D. University of Michigan, Ann Arbor, 1883; a Fellow of the American Medical Association; one of the most prominent practitioners of Allen County, Ohio; vice-president of the local University of Michigan Alumni Association; once president of the Lima Progressive Association; a member of the Board of Trustees of the District Tuberculosis Hospital; formerly president of the Allen County Medical Society and Northwestern Medical Society, and vice-president of the Ohio State Medical Association; died at his home in Lima, December 27, from pneumonia, aged 57. At a meeting of the Allen County Medical Society, January 1, resolutions of sorrow and regret were adopted, and the members of the society and medical profession of Lima and vicinity attended the funeral in a body.

Charles Phelps, M.D. College of Physicians and Surgeons, New York City, 1858; for more than forty years a member of the visiting staff of St. Vincent's and Bellevue hospitals; acting assistant surgeon, U. S. A., during the Civil War; for several terms president of the New York State Medical Association, and twice Health Officer of the Port of New York; died at the home of his son in New York City, December 30, from pneumonia, aged 79.

Emma E. Musson, M.D. Women's Medical College of Pennsylvania, Philadelphia, 1883; a Fellow of the American Medical Association; clinical professor of otology in her Alma Mater; a member of the staff of the Women's Hospital, Women's West Philadelphia Hospital and Amy Barton Dispensary; who had done much research work on bronchoscopy; died at her home in Philadelphia, December 29, from pneumonia, aged 52.

Henry Stier Pole, M.D. Washington University, Baltimore, Md., 1880; a Fellow of the American Medical Association; and a recognized authority on the therapeutic qualities of the waters of Virginia Hot Springs, where he had practiced for forty years; president of the Bath County, Va., National Bank; died at the home of his daughter in Lewisburg, W. Va., December 28, from heart disease, aged 66.

Irving Cornelius Rankin, M.D. University of Pennsylvania, Philadelphia, 1895; a member of the Ohio State Medical Association; gynecologist of the Akron City Hospital, and surgeon to the Northern Ohio Traction Company; for three years city physician; died at his home in Akron, January 1, from nephritis, aged 42.

Zero Marx, M.D. Chicago Homeopathic Medical College, 1894; president of the Zero Marx Sign Company, Chicago; died in St. Mary's Hospital, Rochester, Minn., December 31, from chronic nephritis, aged 67.

Frederick Carl Busch, M.D. University of Buffalo, N. Y., 1897; a Fellow of the American Medical Association; professor of physiology in his Alma Mater, and a member of the staff of the New York State Cancer Laboratory, Buffalo; died in that city, January 3, from malignant disease for which operation had been performed six weeks before without avail, aged 40.

Tertia Claire Wilton Little, M.D. Women's Medical College of Baltimore, 1893; of Letchworth Village, Thiells, N. Y.; formerly assistant physician to the New England Women's Hospital, Boston, and the Massachusetts State Hospital, Taunton; died in the Women's Hospital in the State of New York, New York City, October 25, after a surgical operation.

Daniel P. Deming, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1871; Long Island College Hospital, Brooklyn, 1883; a member of the Michigan State Medical Society; a veteran of the Civil War; proprietor of a hospital in Cass City; died at his home, December 22, from septicemia due to an operation wound, aged 69.

Thomas Ellwood Parker, M.D. Hahnemann Medical College, Philadelphia, 1880; lecturer on pediatrics in the West Jersey Homeopathic Hospital, Camden; secretary of the Board of Education of Woodbury, N. J.; died suddenly at his home in that city, December 29, from cerebral hemorrhage, aged 59.

Ephraim Magoon (license, Missouri, 1893); a veteran of the Civil War; a practitioner of St. Louis for forty-nine years, who fell downstairs at his home, December 2, fracturing the seventh cervical vertebra, died in the St. Louis Mullanphy Hospital, December 29, aged 71.

Francis Reder (license, Illinois, 1877); a practitioner since 1852; for many years a resident of St. Louis, but for the last few months living on a farm at New Athens, Ill.; died in the Deaconess Hospital, St. Louis, December 28, from chronic interstitial nephritis, aged 84.

James Glasgow Haywood, M.D. Memphis Hospital Medical College, 1883; of Brownsville, Tenn.; a practitioner since 1846; a Confederate veteran; at one time president of the Haywood County Medical Society; died in St. Joseph's Hospital, Memphis, December 29, aged 87.

Marshall R. Borst (license, Kansas, 1901); a practitioner for twenty-five years and a member of the Kansas Medical Society; at one time Health Officer of Mitchell County; died at his home in Glen Elder, December 24, from cerebral hemorrhage, aged 58.

Samuel Perkey, M.D. University of Michigan, Ann Arbor, 1862; formerly a practitioner of Eaton County, Michigan; for twenty-five years a member of the medical profession in Chicago; died at his home in Los Angeles, Cal., December 29, aged 73.

Ellsworth Jay Hyatt, M.D. Starling Medical College, Columbus, O., 1888; a practitioner of Nevada since 1906, and a rancher of Rebel Creek; died at the Humboldt County Hospital, Winnemucca, December 20, from cerebral hemorrhage, aged 51.

Sara Thomas Elliott, M.D. College of Physicians and Surgeons, Chicago, 1900; a Fellow of the American Medical Association; of Lake Worth, Florida; died in the Miami City Hospital, November 26, from cerebral hemorrhage, aged 46.

Thomas Lyman Perkins, M.D. Harvard Medical School, 1880; formerly surgeon to the Salem, Mass., Hospital; later a practitioner of Washington, D. C., and Springfield, Ill.; died in his apartment in the latter city, December 26, aged 62.

James Alexander Hutton Curts, M.D. Trinity Medical College, Toronto, 1899; a member of the Medical Society of New Jersey; visiting physician to St. Joseph's Hospital, Paterson; died at his home in that city, December 31, aged 36.

William F. Greene, (license, Arkansas, 1903); a representative to the legislature from Benton County in 1901; formerly a practitioner of Pea Ridge; died at his home in Prairie Grove, December 20, from acute gastritis, aged 57.

Sylvanus Person, M.D. Jefferson Medical College, 1882; a Fellow of the American Medical Association; and a large land owner of Stanton County, Neb.; died at his home in Stanton, December 24, from nephritis, aged 56.

William James McPheeters, M.D. Western Pennsylvania Medical College, Pittsburgh, 1903; of Hookstown, Pa.; died December 11, in Orlando, Fla., where he had gone on account of disease of the lungs, aged 38.

Frederick C. Hageman, M.D. Rush Medical College, 1870; formerly a practitioner of Chicago; died in an infirmary in Mobile, Ala., December 14, aged 69.

Johannes G. Oosterbeck, M.D. Rush Medical College, 1904; formerly of Hysham, Mont.; a member of the staff of Peoria State Hospital for five years; died at the home of his mother in Chicago, January 8, aged 37.

Charles William Stodder, M.D. Tufts College Medical School, Boston, 1898; a Fellow of the American Medical Association; died at his home in Marshfield Hills, December 12, from aneurysm of the aorta, aged 48.

Edgar Patton McCollum, M.D. University of Alabama, Mobile, 1893; a Fellow of the American Medical Association; once mayor of Greensboro, Ala.; died at his home in that city, January 2, aged 41.

John Fry, M.D. Cleveland University of Medicine and Surgery, 1863; College of Physicians and Surgeons of Ontario, 1893; died at his home in Selkirk, Ont., October 2, from senile debility, aged 77.

James Houston, M.D. University of Michigan, Ann Arbor, 1867; state senator from Wayne County from 1883 to 1887; died at his home in Ypsilanti, December 18, from cerebral hemorrhage, aged 81.

Robert Roy Ross, M.D. Trinity Medical College, Toronto, 1889; a member of the Washington State Medical Association; formerly of Nebraska; died at his home in Seattle, December 18, aged 49.

James A. J. McDonald, M.D. Eclectic Medical Institute, Cincinnati, 1883; College of Physicians and Surgeons, San Francisco, 1898; died at his home in San Francisco, December 26, aged 62.

John S. Caulkins (license, Michigan), a member of the Michigan State Medical Society; for sixty-six years a practitioner; died at his home in Thornville, December 29, aged 91.

Thrond J. Eltun, M.D. Hamline University, Minneapolis, 1904; a Fellow of the American Medical Association, of Velva, N. D.; died November 6, from tuberculosis, aged 42.

Amos Henry Elliott, M.D. New York Homeopathic Medical College, New York City, 1888; died at his home in Brooklyn, December 12, from cerebral hemorrhage, aged 73.

Ernest Wuestefeld, M D. Western Reserve University, Cleveland, 1868; a practitioner of Toledo for forty-three years; died at his home in that city, December 24, aged 70.

Robert Henderson McCarty, M.D. Hahnemann Medical College, Philadelphia, 1895; a veteran of the Civil War; died at his home in Roanoke, Va., December 27, aged 72.

Joseph Howard Schenck, M.D. Jefferson Medical College, 1869; of Philadelphia; died at his home in Wynnewood, Pa., December 28, from cerebral hemorrhage, aged 65.

James M. Scott, M.D. University of Virginia, Charlottesville, 1878; a memoer of the Medical Society of Virginia; died at his home in Raccoon Ford, December 29.

Samuel John Davis, M.D. Atlanta (Ga.) Medical College, 1882; for many years a practitioner of Albertville, Ala.; died in Tuscaloosa, about December 17, aged 61.

John S. Walker, M.D. University of Pennsylvania, Philadelphia, 1871; died at his home in Philadelphia, November 14, from valvular heart disease, aged 66.

Noel Gano Mussey, M.D. Medical College of Cincinnati, 1909; of Maineville, Ohio; died at the home of his mother in Glendale, Cincinnati, December 9, aged 38.

Joseph P. Johnson, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1867; died at his home in Hightstown, N. J., December 19, aged 77.

George Wallace Nelson, M.D. Castleton (Vt.) Medical College, 1861; died at his home in Orwell, N. Y., December 15, from cerebral hemorrhage, aged 78.

Andrew Smith (license, Allegheny County, Pa., 1881); for about forty years a practitioner, died at his home in Carnegie, Pa., December 22, aged 78.

James J. Mensch, M.D. Pennsylvania Medical College, Gettysburg, 1856; died at his home in Pennsburg, Pa., about December 13, aged 83.

William T. Durrett, M.D. University of Louisville, 1879; died at his home in Louisville, December 13, from nephritis, aged 58.

George M. Zigler, M.D. Jefferson Medical College, 1897; died at his home in Nicetown, Pa., December 24, from heart disease, aged 52.

Charles M. Vertrees (license, Illinois State Board of Health, 1878); died at his home in Jacksonville, December 22, aged 76.

Hugh Kelly, M.D. Tulane University, New Orleans, 1886; died at his home in New Orleans, December 22, aged 54.

Association News

THE ATLANTIC CITY SESSION

Local Committee of Arrangements

The annual session of the American Medical Association for 1914 will be held at Atlantic City during the fourth week in June. The House of Delegates will convene Monday, June 22, and the Scientific Assembly—the Sections—Tuesday, June 23.

The following are the officers of the local Committee on Arrangements: William Edgar Darnall, chairman; E. C. Chew, treasurer, and Henry T. Harvey, secretary.

The chairmen of subcommittees are:

Finance	George Scott
Entertainment	William J. Carrington
Section Entertainment	W. E. Jonah
Hotels	Thomas D. Taggart
Halls and Meeting-Places	Walt P. Conaway
Section Meetings	Byron G. Davis
Programs	C. Coulter Charlton
Printing	Walter Reynolds
Badges	E. H. Harvey
Scientific Exhibit	I. E. Leonard
Registration	William Martin
Information	Richard Bew
Alumni Entertainments	Joseph C. Marshall
Post-Office and Telephones	C. Garrabrandt
Commercial Exhibit	E. Guion
Ladies Committee	Mrs. E. H. Harvey

The Color of Danger-Signals

To the Editor:—The wide-spread interest in this question, among both the medical profession and the public at large, is my excuse for referring once more to Dr. Patterson's article, which you discussed in an editorial (Nov. 8, 1913, p. 1724). I have also seen comments on the same article in a number of our popular magazines.

To my mind, the arguments advanced by Dr. Patterson for substituting blue and yellow for green and red, as the colors of danger-signals, are not sound when examined from a scientific point of view. Dr. Edmonds answers the question admirably in a way easily understood by any one (THE JOURNAL, Nov. 29, 1913, p. 1999). On a purely scientific basis we can explain why blue and yellow would be extremely poor substitutes for green and red. Ordinary blue glass transmits many red rays besides the blue ones, leaving about 4 per cent. of the naked light behind it to pass through it; while by a glass of fairly pure blue, the luminosity would be reduced to about 2 per cent. This luminosity in foggy weather would be reduced to nothing. A yellow signal would be luminous enough, but under certain atmospheric conditions would appear too much like white.

Green transmits from 10 to 20 per cent. of the luminosity of the light behind it, while red glass also allows about 10 per cent. of the light behind it to pass through. In our days of high speed, both on land and on sea, it is highly necessary to be able to see and distinguish the colors of lights at a distance of several thousand feet. In certain conditions of the atmosphere, blue and yellow cannot be distinguished as such at this distance, and the danger of collisions would be greatly increased if these colors were to be used as signals. The important thing to be considered is this, that the main object is not to use colors which will be most easily distinguished by the comparatively small number of color-blind persons (less than 4 per cent. of the entire population) under the most favorable conditions, but to use such colors as will be most easily seen by the 96 per cent. of normal-sighted persons under the most unfavorable conditions.

This matter is, in fact, only a more conclusive argument for prohibiting color-blind persons from holding any position in which a quick and accurate perception of color is an imperative necessity.

CHARLES P. SMALL, M.D., Chicago.

Blood Transfusion in the Seventeenth Century

To the Editor:—Apropos of Dr. Michael Campbell's
and quotation from Pepys' diary in regard to transfusi
blood (THE JOURNAL, Jan. 10, 1914, p. 147), it may in
readers to have their attention called to an Italian phy
named Francesco Folli. He was born at Poppi in 162
came from a family which was prominent in public a
He practiced medicine for some years at Bibbiena. Th

caused to be forbidden by the authorities."

ROWLAND COX, JR., M.D., Paterson, N.

Associations of Physicians for the Study of Tubercul

To the Editor:—A study of the existing antituberc
machinery in various cities discloses the absence of s
physicians' associations for the study of the medical si
the problem. The lack of such associations that would
together, at stated intervals, medical men interested i
disease for the purpose of discussing its important p
seems to be a grave omission in the general scheme, con
ing the importance of the medical profession as a fact
the antituberculosis movement, as well as the existence
large number of medical questions pertaining to tuberc
on which the collective judgment of the profession ca
formulated only through continuous discussion and stud

To meet this need, all Chicago physicians connected
tuberculosis sanatoriums, hospitals and dispensaries, as
as medical men interested in the study of the disease
invited, under the auspices of the Chicago Tuberculosis
tute, to a luncheon at the City Club, Feb. 11, 1913, to a
the first meeting of the so-called "Tuberculosis Study Ci
It was planned that the time between 12:15 and 1 o'
be given to the luncheon, and the hour between 1 and
the presentation of some important medical phase of tub
losis by some one who has made a thorough study of it.
success of the first luncheon led to others. The meetings
proved to be exceedingly popular, bringing together fo
first time, at regular intervals, physicians interested in
study of tuberculosis.

The experience of the last ten months has brought ou
following points, which are probably important in conne
with the organization of such associations:

1. Time should not be wasted in preparation of elab
by-laws and constitutions. A man well posted on a ce
phase of the disease should be announced as speaker fo
first meeting. The by-laws may be prepared later.

2. The best time for meetings of physicians is the
hour. Luncheon is served from 12:15 to 1, and the ad
and discussion occupy the time from 1 to 2. Adjourn
should be made promptly at 2. *Meetings should be held*
a month.

3. Written papers should be barred; notes are permis
The subject should be thoroughly handled by a well-posted

We are now in our tenth month of existence and it is evident that our organization has done a great deal of good in the direction of adjusting differences of opinion, stimulating study and bringing closer together the medical men interested in the disease. Attendance at our meetings has averaged from 55 to 85. It may be desirable that the plan we have put in operation in Chicago should be studied by medical men in other cities. A greater adjustment of views of the medical profession on the subject of tuberculosis, and also a further incentive to study of this wide-spread disease, are greatly needed.

The physicians' association should be affiliated with the local antituberculosis organization and through that with the national antituberculosis association.

THEODORE B. SACHS, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

STATUTES REGULATING MARRIAGE

To the Editor:—Please give a summary of the recently enacted marriage laws of Wisconsin and Michigan. What other states have passed such laws?

E. J. ANGLE, M.D., Lincoln, Neb.

ANSWER.—The statutes of Michigan provide, in addition to the prohibition within the usual degrees of consanguinity, that "no insane person, idiot, or person who has been afflicted with syphilis or gonorrhea and has not been cured of the same shall be capable of contracting marriage." Any person violating this section shall be guilty of felony, and in all prosecutions under the act the husband shall be examined as a witness against his wife, and a wife shall be examined as a witness against her husband whether they consent to such examination or not. Physicians shall also be compelled to testify as to their knowledge of the conditions of both parties with reference to the diseases named. It is also provided that "no person who has been confined in any public institution or asylum as an epileptic, feeble-minded, imbecile or insane patient shall be capable of contracting marriage without, before the issuance by the county clerk of the license to marry, filing in the office of the said county clerk a verified certificate from two regularly licensed physicians of this state that such person has been completely cured of such insanity, epilepsy, imbecility or feeble-mindedness, and that there is no probability that such person will transmit any of such defects or disabilities to the issue of such marriage." An attempt in the last session of the Michigan legislature to enact a law requiring that all applicants for marriage licenses should present certificates of health from qualified physicians failed of passage.

The new Wisconsin act of Aug. 2, 1913 (effective Jan. 1, 1914), with reference to marriage was discussed in an editorial in THE JOURNAL, Dec. 27, 1913, p. 2306. This is an amendment to marriage laws already on the statute books with reference to the prevention of venereal diseases, and provides that "all male persons making application for license to marry shall at any time within fifteen days prior to such application be examined as to the existence or non-existence in such persons of any venereal disease; and it shall be unlawful for the county clerk to issue any license to marry to any person who fails to present and file with such clerk a certificate setting forth that such person is free from acquired venereal disease so nearly as can be determined by physical examination and by the application of the recognized clinical and laboratory tests of scientific search." The form of the physician's certificate is prescribed and it must be filed with the application for a marriage license. Physicians who make examinations must be duly licensed to practice in the state, be of good moral character and scientific attainments, and shall be at least 30 years of age. The fee allowed by the law for the examination is not to exceed the sum of $3. The county physicians may make such examinations for indigent persons free of charge. In case of dispute in regard to the finding, the state laboratory shall make an examination of material submitted by the first examiner, and the findings of the state laboratory shall be accepted as final with reference to the presence or absence of venereal disease. In case of refusal of a certificate, appeal may be made to the county court. It is also provided that in case a physician makes a false statement in the certificate, he shall be guilty of perjury, and a conviction under this clause of the act shall automatically revoke the license of the physician.

North Dakota also has a law, effective July 1, 1913, requiring the affidavit of at least one duly licensed physician showing that applicants for marriage license are not feeble-minded, imbeciles, epileptics, insane persons, common drunkards, or persons afflicted with pulmonary tuberculosis in its advanced stages, and in addition that the male contracting party is not afflicted with any contagious venereal disease. For making the examination of either party and the affidavit the physician is allowed a fee not to exceed $2.

The Colorado act of 1913 provides that "no license to marry shall be issued where either of the contracting parties is an idiot, imbecile, of unsound mind, or under guardianship as a person of unsound mind, epileptic, insane, a habitual user of narcotic drugs, a habitual drunkard or habitual criminal, or who has been insane within five years, unless the female party to such marriage is over the age of 48 years or the male party thereto has been sterilized." No license to marry shall issue "when either of the parties is afflicted with a transmissible tubercular or venereal disease, or who at the time of making the application is under the influence of an intoxicating liquor or narcotic drug." Applicants for license to marry shall file with the county clerk "an affidavit of at least one duly licensed physician other than the person seeking the license, showing that the contracting parties are not idiotic, imbecile, of unsound mind, or under guardianship as persons of unsound mind, epileptic, insane, narcotic or drug habitués or habitual drunkards, or afflicted with a transmissible tubercular or venereal disease," or that one of the parties has been sterilized.

Oklahoma by an act passed in 1913 likewise requires the certificate of a physician as to the fitness of the parties to enter into the marriage contract.

Other states which recently have passed laws with the design of preventing venereal disease through marriage are Utah, Washington, Indiana and Pennsylvania, but these states do not require a physician's certificate. In the last-named state an oath must be made by persons contemplating matrimony to the effect that they are physically fit for marriage, and no license shall be issued to any person who is an imbecile, epileptic, a person of unsound mind or under guardianship as a person of unsound mind, nor to any person who within five years has been an inmate of a county asylum or a home for indigent persons unless the cause of such condition has been removed and the applicant is able to support a family. Licenses shall not be granted to persons under the influence of liquor or narcotic drugs. A discussion of state regulation of marriage will be found in THE JOURNAL, May 17, 1913, p. 1562, in which the marriage laws of states other than those above named are taken up.

SERUM AND VACCINE TREATMENT OF TYPHOID

To the Editor:—1. Does the serum injection for typhoid favorably modify the course of the disease after it has become established?

2. Does the serum, if injected, make a person immune to typhoid, and if so for how long does the immunity last?

3. How is the serum obtained?

I understand that the serum [illegible] rs in the army, but wish to obtain more [illegible] one gets from newspapers.

[illegible] Mich.

ANSWER.—We must, of course, distinguish between the serum treatment of typhoid and the vaccine treatment. Our correspondent inquires with reference to the serum treatment.

1. The principal serum used in the treatment of typhoid is that of Chantemesse. Chantemesse reports very good results from his treatment, but these have not been confirmed by other authors. It may be said that the evidence with reference to this form of treatment is insufficient for positive conclusions to be drawn from it. It has been used altogether, or nearly so, as a curative treatment.

2. So far as we know the immunity produced by it is quite temporary.

3. The serum is obtained from horses injected with the typhoid bacillus.

The statement of the correspondent that he has understood that the serum treatment has done wonders in the army evidently refers to the vaccine treatment which has been used in the United States Army. This treatment is a prophylactic vaccination to prevent the occurrence of the disease. The vaccine employed is an emulsion of killed typhoid bacilli produced by heating cultures of that organism. Such cultures have been used for the treatment of typhoid fever and favorable results have been reported, but there is no agreement among clinicians as to the value of this form of treatment. It is, however, an effective prophylactic. The immunity conferred on healthy persons lasts about two years and in some cases longer.

LITERATURE ON RECENT MEDICAL DISCOVERIES

To the Editor:—I wish to prepare a paper on new discoveries in medicine. If you can send me any material or refer me to literature that will help me, I shall be very glad indeed. W. A. N.

To the Editor:—What do you consider the most important discoveries in medicine either curative or preventive in 1913? Please name the subject, refer me to literature or comment on it.

G. F. Jones, M.D., Georgetown, Del.

Answer.—The following is a list of articles referring to recent discoveries of importance:

Noguchi, H., and Moore, J. W.: Demonstration of Treponema Pallidum in Brain in Cases of General Paralysis, *Jour. Exper. Med.*, February, 1913; abstr., The Journal, Feb. 22, 1913, p. 627.

Spirochaeta Pallida in the Brain in General Paralysis, Current Comment, The Journal, March 29, 1913, p. 1002.

Judd, C. C. W.: Serum Diagnosis of Pregnancy, The Journal, June 21, 1913, p. 1947.

Rosenow, E. C.: Etiology of Articular and Muscular Rheumatism, The Journal, April 19, 1913, p. 1223.

Fischer, J.: Abderhalden's Serodiagnosis of Mental Diseases, Deutsch. med. Wchnschr., Oct. 30, 1913; abstr., The Journal, Dec. 6, 1913, p. 2111.

UNDESCENDED TESTICLE

To the Editor:—In a man aged 23, the right testicle and right corpus cavernosum are normal. The left testicle is undescended, and the left corpus is only partially developed, making erection of penis perfect on right side, and less than 50 per cent. efficient on the left, the organ being curved as in chordee.

1. In double castration before puberty, or if both testicles remain in the abdomen, would neither corpus develop?
2. In single castration before puberty, or with one undescended testicle, does lack of development result in the corpus of the corresponding side?
3. In short, is it a physiologic law that each testicle controls the development of the corpus cavernosum on its respective side?
4. Is it possible for spermatozoa to mature, and a man be sexually potent when both testicles are undescended?

D. W. Wheelwright, M.D., Woodward, Iowa.

Answer.—1. With castration before puberty, the external genitals remain small in development.

2 and 3. It is not generally thought that the development of the testicles governs the growth of the corpora cavernosa. With undescended testicles, all things are possible so far as development and function of the genital organs are concerned, depending on a number of factors. Testicles may be quite normal in every way and still be undescended.

4. Yes.

EFFECT OF ARSENIC

To the Editor:—Please answer the following:

1. What is the effect of long-continued and large doses of arsenic on the individual's resistance to disease?
2. Is it or is it not true that the arsenic eaters of Styria and Tyrol enjoy long life and good health, and apparently resist disease as well as other persons who use no arsenic?
3. What is the longest time (months or years) on record of the finding of arsenic in the urine or body after its administration by mouth?
4. Does not the reliability of statements of the finding after months or years become lessened in the light of reports that arsenic has been recovered from the urine when it had never been administered by mouth or injection?

Hugh S. Maxwell, M.D., Lisbon, Ohio.

Answer.—1. So far as we can learn there has been no determination of the effect of large doses of arsenic on the individual resistance. Presumably, like other forms of poisoning, it would reduce it.

2. The reports of the arsenic-eaters of Styria and Tyrol indicate that they were strong and apparently healthy men. We find no statements indicating their length of life.

3. Arsenic has been found in the urine ninety-three days after its administration. The statements as to the length of time that it can be found in the soft parts are derived from necropsies following single poisonous doses. The latest period at which it has been found in the soft parts is fourteen days, but it has been found in the bones six weeks after the taking of the poison.

4. The most careful investigations of arsenic in the normal body have been those of Gautier. According to him, arsenic is not found in normal urine, that is, when arsenic has not been ingested.

BOOKS ON HEREDITY AND HYGIENE

To the Editor:—Please publish a list of books on eugenics and heredity, and one on hygiene and sanitation, especially of the schools. F. E. Redman, M.D., Mott, N. Dak.

Answer.—Recent works on these subjects include the following:

Goddard, H. H.: The Kallikak Family, a Study in Heredity of Feeble-Mindedness, Macmillan Company, 66 Fifth Avenue, New York, price $1.50.

Bateson, W.: Mendel's Principles of Heredity, G. P. Putnam's Sons, 27-29, West Twenty-Third Street, New York, price $3.50; Problems of Genetics, Yale University Press, New Haven, price $4 net.

Walker, C. E.: Hereditary Characters and Their Mode of Transmission, Longmans, Green & Co., 91 Fifth Avenue, New York, price $2.40.

Saleeby, C. W.: Parenthood and Race Culture, Moffart Yard & Co., New York, price, $2.50.

Punnett, R. C.: Mendelism, Macmillan Company, 66 Fifth Avenue, New York, price $1.25.

Winship, A. E.: Jukes-Edward, R. L. Myers & Co., 401 West Market Street, Harrisburg, Pa., price 50 cents.

Rosenau, M. J.: Preventive Medicine, D. Appleton & Co., 29-35 West Thirty-Second Street, New York, price $6.

Harrington: Practical Hygiene, Lea & Febiger, 706-710 Sansom Street, Philadelphia, price $4.25.

Dresslar, F. B.: School Hygiene, Macmillan Company, 66 Fifth Avenue, New York, price $1.25.

Pyle: Personal Hygiene, W. B. Saunders Company, 925 Walnut Street, Philadelphia, price $1.50.

Bergey: Handbook of Hygiene, John Wiley & Sons, New York, price $1.50.

Sedgwick: Principles of Sanitary Science and the Public Health, Macmillan Company, 66 Fifth Avenue, New York, price $3.

ANTI-CIGARETTE LEAGUE TREATMENT

To the Editor:—I understand that the Anti-Cigarette League of Chicago has a treatment for cigarette-smoking. Is this treatment successful? What is the treatment?

Henry C. Cadwell, M.D., St. Croix Falls, Wis.

Answer.—The treatment advised by the Anti-Cigarette League consists, first, in careful regulation of the diet, particularly the exclusion of meat for a time. The diet for the first two weeks consists exclusively of fruits, well-cooked cereal foods and milk. Eliminative baths, preferably the Turkish bath, will assist in rapidly getting rid of the stored-up nicotin. The second and third parts of the treatment are the chewing of the gentian root between meals, and the washing of the mouth with a 0.25 per cent. solution of silver nitrate after each meal. This is continued, if necessary, for one week. The silver nitrate, it is claimed, combines with nicotin so as to render it extremely distasteful.

TRANSMISSION TO FETUS OF IMMUNITY TO SMALL-POX

To the Editor:—Please inform me if an active case of small-pox in the mother, eight months pregnant, conveys an immunity in the child. The patient in question was vaccinated twice. Both vaccinations were negative, but the patient later developed varioloid.

D. M. C.

Answer.—Small-pox may be conveyed to the fetus through the placenta, and in this way the fetus may experience the disease; if recovery takes place, immunity will be acquired as in cases of extra-uterine disease. The fetus does not always take the disease *in utero*, and in such cases we do not know that there is any evidence of the transmission of immunity.

CALCIUM CREOSOTE—SYRUP AMMONIUM HYPOPHOSPHITE

To the Editor:—1. I should like to ask your opinion of Calcium Creosote, so-called, that is being offered by several houses. Is it a good way to administer creosote?

2. Is Syrup Ammonium Hypophosphite a good way to administer ammonium in bronchitis?

N. F. Cheever, M.D., Greenfield, N. H.

Answer.—1. We are not able to advise regarding this matter.

2. Yes.

Miscellany

Bradycardia in Intestinal Disease.—M. Loeper (*Presse méd. belge*, 1913, lxv, 863) cites a number of typical cases. In some the pulse was 36-42 or in this vicinity, the bradycardia coming on as it were spontaneously in the course of an aggravation of long-existing vague intestinal trouble in persons inclined to be neurotic. In other cases the bradycardia was secondary to an acute or subacute intestinal affection, such as gangrenous appendicitis. In one case the pulse was 54 or 56, but the general condition was at first quite fairly good and the cardiovascular apparatus apparently intact. Necropsy disclosed a cancer at the ileocecal valve. Loeper states that bradycardia in these intestinal cases is intermittent and transient, disappearing as the intestinal affection is cured. The bradycardia is generally accompanied by malaise, dizziness and tendency to syncope, resembling an incomplete form of Stokes-Adams. Subcutaneous injection of 0.001 gm. of atropin sulphate does not modify bradycardia of organic origin, but the pulse starts up at once when the bradycardia is of nervous origin. Compression of the eyeball renders the pulse still slower with nervous bradycardia while it does not modify the organic. Certain facts observed suggest the possibility that some irritation or affection of the medulla oblongata or pneumogastric system may be the primal cause of both the intestinal disturbance and the bradycardia. Treatment of the bradycardia in either case, Loeper says, should be with valerian and belladonna (0.05 gm. and 0.02 gm.), taken three or four times in the twenty-four hours, the patient staying in bed to prevent injury from vertigo or syncope. In severe cases atropin should be given. Hot or alcoholized compresses to the abdomen soothe both the vascular and the nervous elements. The cause must be sought and removed, but drastic measures should be avoided.

Rape in Young Girls.—In an article in *International Clinics*, 1913, ii and iii, on this subject, Gurney Williams states it as his belief that the crime of rape is on the increase. He says that neither the medical nor the medicolegal aspects of the crime are properly understood by physicians, and that in consequence many mistakes are made and innocent persons compelled to suffer. He criticizes the superficial examinations and investigations made by physicians, the methods of dealing with these cases by lawyers and the courts and the laxity of parents in the matter of proper teaching and safeguards, and points out the rôle of modern industrial and living conditions in the promotion of this form of crime. The medical and the medicolegal sides of the question are discussed and illustrative cases are given showing how grievous errors may arise in the investigation and handling of these cases, and much good advice derived from a large experience is given as to how the physician should proceed so that the truth may be arrived at and no injustice be done to either party. To the physician, the lawyer, the courts and to sociologists these papers should be of the highest interest.

Local Cold Storage Warehouses in Canada.—J. A. Ruddick, Dairy and Cold Storage Commissioner of Canada, at the Third International Congress of Refrigeration, described the Canadian law under which local cold storage plants are subsidized. In 1907 the Canadian Parliament passed a law which authorizes the Minister of Agriculture to enter into contracts for the payment of subsidies on public cold storage warehouses erected under certain conditions. Before this law came into force, the larger centers had been provided with cold storage facilities, but under this legislation the erection of comparatively small local warehouses situated in the producing centers of Eastern Canada has been stimulated. In this way, storage facilities are provided as nearly as possible to the point of production and the goods are placed in cold storage with the least possible loss of time or chance for deterioration. The main advantage in having local cold storage warehouses at points of production is that such a plan enables the producer or dealer to place his perishable goods in safe-keeping with the least possible delay. The prejudice which exists in some quarters against cold-stored foods has its root very largely in the fact that these foods are often out of condition before they reach the warehouse. The local cold storage plant is, in Ruddick's judgment, a safeguard against such conditions arising. For egg storage and where extremely low temperatures are not required, the system is giving very good satisfaction with a low cost of operation. The regulations made under the act provide for the inspection of all cold storage warehouses which receive the government subsidy. The inspection relates to the sanitary condition of the establishment and the manner in which it is conducted. If the inspector's report is unsatisfactory, the instalments of the subsidy still due may be withheld.

Opticians' Mistakes.—Durand (*Ann. Ophth.*, 1913, xxii, 673) states that it is an every-day occurrence for patients to go from one ophthalmologist to another and obtain no relief because of error by the optician in filling the prescription. As proof for this assertion he advances the following statistics: Three hundred and fifty lenses obtained as a result of writing to thirty-eight ophthalmologists whose prescriptions had been filled by forty-five opticians were compared with a control series of 250 lenses, from prescription of one ophthalmologist filled by one optician. The latter was bound by an agreement that any lens not accurately coinciding with the prescription would not be accepted. In the former group there were ninety-one accurate lenses, or a total of 26.03 per cent.; in the latter group 194 accurate, or a total of 77.6 per cent. "That absolute accuracy is practically as well as scientifically worth while," says Durand, "is being demonstrated daily in the practice of those men who are not satisfied with any inferior work." The assertion has been made that absolute accuracy is not necessary because few patients keep their glasses straight for any length of time. If the science of refraction is really a science, then, this is indeed a ridiculous assertion. The filling of the prescription is based on an exact science, and the experience of those who have studied the matter shows that any good optician can fill prescriptions accurately if he takes time and trouble. If the ophthalmologist is indifferent and willing to accept "just as good" productions, no discussion is necessary; but, if he accepts the responsibility of doing his best for the patient, he will then see to it, not simply that a prescription is as good as he can make it, but also that it is filled accurately.

Meningeal Hemorrhage in Childhood.—Meningeal hemorrhage is met in newly born infants who have become infected, and in connection with hemorrhagic states. It may also follow strain or effort in presence of meningeal irritation, and is almost always of venous origin in infants. In most cases the symptomatology is reduced to somnolence and a tendency to coma. Conjugate deviation of the eyes and head is less frequent than in cerebral hemorrhage. Epileptiform convulsions are common and are usually of the jacksonian type. Contracture is usually present, and Kernig's sign is pretty constant. In older children we may meet hemiplegia or monoplegia. Sometimes there is amaurosis or incontinence of urine. The reflexes are exaggerated but should there be hypertension of the cerebrospinal fluid they may be abolished. Vomiting is common, and respiration is often dissociated, as in tuberculous meningitis. The temperature may rise and reach 104 F., or more when death is imminent. Then, too, there are varied latent unrecognizable forms. Two types have been described in the newly born — the blue and the white. The latter form is the more serious, and the victim succumbs with extensive effusions of blood. Lumbar puncture gives issue to a more or less manifestly blood-stained fluid. Prognosis is not quite so grave as it used to be, and recovery is not uncommon, though the forecast must be guarded in respect to the child's future. Epilepsy is very apt to supervene later on in life. The patient should be kept very quiet, with ice to the head; the limbs are wrapped in wadding, the bowels are cleared with enemas and aperients, and recourse should be had to lumbar puncture except in hemorrhagic subjects. Bromid is usually of benefit in these cases by diminishing cerebral congestion.—Hutinel in *Med. Press and Circular.*

Medical Education and State Boards of Registration

COMING EXAMINATIONS

KANSAS: Topeka, Feb. 9-11. Sec., Dr. H. A. Dykes, Lebanon.
MISSOURI: Jefferson Hotel, St. Louis, Feb. 9-11. Sec., Dr. J. A. B. Adcock, Jefferson City.
NEBRASKA: Lincoln, Feb. 11. Sec., Dr. H. B. Cummins, Seward.
NEW YORK: Jan. 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Albany.

Georgia October Report

Dr. C. T. Nolan, secretary of the State Board of Medical Examiners of Georgia, reports the written examination held at Atlanta, Oct. 14, 1913. The number of subjects examined was 10; total number of questions asked, 100; percentage required to pass, 80. The total number of candidates examined was 22, of whom 15 passed and 7 failed. Six candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Alabama	(1911)	84.2
Atlanta School of Medicine	(1913)	80
University of Georgia	(1913)	85.1
University of Louisville	(1912) 80; (1913)	80.5, 81.2
Tulane University	(1913)	88
Johns Hopkins University	(1913)	80
Maryland Medical College	(1912) 80.5; (1913)	80.2
University of Maryland	(1913)	87.2
Leonard Medical School	(1912)	89.5
Meharry Medical College	(1912) 81.2; (1913)	80.2, 83.2

FAILED

College	Year Grad.	Per Cent.
University of Georgia	*(1912)*	73.2
Maryland Medical College	(1912)	71.2
Chattanooga Medical College	(1910)	71.3
Meharry Medical College	(1908) 69.3; (1912)	64.1, 68.1, 72.2.

Book Notices

Problems of Genetics. By William Bateson, M.A., F.R.S., Director of the John Innes Horticultural Institution. Cloth. Price, $4. Pp. 258, with illustrations. New Haven: Yale University Press, 1913.

The purpose of Bateson's lectures, as here reproduced, was to discuss some of the familiar phenomena of biology in the light of knowledge acquired by the methods of analysis based on the observations which Mendel offered to the world in two papers, in 1866 and 1869. The lectures were delivered in 1907, but their publication was delayed because Bateson desired to produce first his "Mendel's Principles of Heredity," which he did in 1909, offering in that work translations of the two epochal papers before mentioned. The delay in the issue of the present book has been fortunate in that Bateson has been able to incorporate many contributions in the field in which he is so original, revealing and broadening a worker.

Bateson reminds us that after 1890 it was perceived that if any serious advance was to be made with the group of problems generally spoken of as the theory of evolution, more direct and penetrating methods of investigation would have to be applied than those which seemed adequate at the time of the general acceptance of Darwin's views. Such methods were to be found in an exhaustive study of the facts of variation and heredity, on which all conceptions of evolution are based. To synthesize a valid theory of evolution these facts had to be examined as phenomena, instead of being merely postulated as axioms; indeed, Darwin had begun such an examination. The terms "variation" and "heredity" have stood for processes so vague that no analysis of them could be contemplated. As soon as systematic inquiry into the natural facts was begun, accepted ideas of variation were discovered to be unfounded. Variation was becoming recognized as a definite and specific phenomenon, affecting different forms of life in different ways, but in all its diversity manifesting regularity. The observation was not essentially novel. Several examples of definite variation had been known to Darwin, but he had been disposed to depreciate their significance. Continued and careful inquiry, however, proved such examples to be more numerous than was supposed, and a discussion of their nature compelled the consideration that the differences by which these definite or discontinuous variations are constituted, again and again approximate and are comparable with the class of differences by which species are distinguished from each other.

By means, then, of the facts of variation, a new light was obtained on the physiologic composition and capabilities of living things. Genetics thus ceases to be merely a method of investigating theories of evolution or of the origin of species, and provides an instrument by which the nature of the living organism may be explored. In the study of non-living matter science began by regarding its external properties, noting only such evidences of chemical attributes and powers as chance revealed; later it came to discover that these casual evidences, rightly interpreted, afford a key to the intrinsic nature of the diversity of matter. In like manner the biologist, having examined those features of living things which ordinary observation can perceive, has come at last to realize that when studied for their own sake, the properties of living organisms in respect to heredity and variation indicate their inner nature and provide evidence of that nature which is obtainable from no other source.

While such ideas as Bateson thus expresses were gradually forming, there came the rediscovery of Mendel's work, through which investigations before only imagined as desirable became easy to pursue. Questions as to the genetic interrelations and compositions of varieties can now be definitely answered. In Mendelism (the essence of which lies in the discovery of unit characters or factors) Bateson believes that we have now the means of analyzing living organisms and distinguishing many of the units or factors which essentially determine and cause the development of the several attributes of those organisms. Bateson assumes in the reader a working knowledge of Mendelism, on the basis of which he discusses the following problems: species and variety;meristic phenomena; segmentation, organic and mechanical; the classification of variation and the nature of substantive variation; the mutation theory; variation and locality; the effects of changed conditions (adaptation, the causes of genetic variation), and the sterility of hybrids.

Stammering and Cognate Defects of Speech. By C. S. Bluemel. Two Volumes. Volume I: The Psychology of Stammering. Vol. II: Contemporaneous Systems of Treating Stammering: Their Possibilities and Limitations. Cloth. Price, $5 net. New York: G. E. Stechert & Co., 1913.

This work is significant from more aspects than one. In the first place the author is a psychologist and also a stammerer, and probably this mysterious disorder has never before been studied introspectively by one skilled in psychologic analysis. The point of view of the book is psychologic. It sets out to find the mental cause for stammering. After recalling certain of the principles of psychology and reviewing at length the psychologic phenomena relating to speech, including the pathologic effect on the speech of the aphasias, it approaches the phenomena of stammering from the foundation thus laid down. So, while disposing of the older theories concerning the origin of stammering, the author arrives at a new theory of causation. He believes the disorder to be dependent on a "transient auditory amnesia," with also, to be sure, accessory physical phenomena. In the course of this very sincere and painstaking study the writer presents for review the gist of much that has heretofore been written on stammering, and also shows the insincerity and unintelligence of much of the institutional treatment prevalent both in Europe and in America. Incidentally also he declares that the best work in treatment is usually that carried on by physicians. A bibliography is appended to the second volume. The book is highly technical but is the most important study of stammering undertaken for many years; it will probably provoke discussion, regardless of the final reception or rejection of the author's theory concerning the cause of the disorder.

Innere Sekretion und Nervensystem. Von H. Eppinger, R. Hirschfeld, A. Leri and Others Volume IV of the "Handbuch der Neurologie," Herausgegeben von M. Lewandowsky. Paper. Price, 24 marks. Pp. 493, with 56 illustrations. Berlin: Julius Springer, 1913.

This volume of Lewandowsky's epoch-making work on the nervous system contains a succinct and yet complete account of the glands with internal secretion in their relation to the nervous system. The following subjects are fully discussed: exophthalmic goiter, myxedema, cretinism, tetany, dystrophia adiposogenitalis, acromegaly, pineal gland disorders, diseases of the adrenals, status thymolymphaticus, agenitalism and hypogenitalism (*insuffisance pluriglandulaire*), nervous manifestations of normal and precocious menopause in relation to the glands of internal secretion, adiposis dolorosa (Dercum's disease) and Paget's disease. Each of the subjects is treated from the clinical point of view mainly, although the theoretical aspect is not lost sight of. This volume, though part of the large work on the nervous system, is complete in itself and will serve as a compendium on the clinical and practical aspects of internal secretory disorders.

Allgemeine Psychopathologie. Ein Leitfaden für Studierende, Aerzte und Psychologen. Von Dr. Karl Jaspers, Wiss. Assist. an der Psychiatrischen Klinik in Heidelberg. Paper. Price, 8.80 marks. Pp. 338. Berlin: Julius Springer, 1913.

In this guide to general psychopathology written for students, physicians and psychologists, general principles are laid down. One might well call it an abbreviated text-book on psychology in which the pathology is kept well in mind. The aim of the writer was not merely to enumerate facts, but to teach his reader how to observe psychopathologically, to question, to analyze and to think psychopathologically. In our opinion the author has written a book worthy of commendation. While it would be impossible to agree with him in every detail, yet his psychology on the whole is sound. This book has the peculiar virtue of leaving one in a dissatisfied state of mind and eager to gain more light; in other words, it stimulates one to pursue the subject further.

Medicolegal

Courts Without Authority to Compel Plaintiffs to Submit to Physical Examinations

(Atchison, Topeka & Santa Fe Railway Co. vs. Melson (Okla.), 134 Pac. R. 388)

The Supreme Court of Oklahoma holds that, in that state, in the absence of a statute or constitutional provision so providing, a trial court has no power to order a plaintiff in an action for damages to his person to submit in advance of or during the trial of the cause to an examination by a physician to be selected by the parties or by the court to ascertain the extent of his injuries, in order that such physician may testify at the trial relative to the plaintiff's injuries. This follows the rule adopted in *City of Kingfisher vs. Altizer*, 13 Okla. 121, where it was held that courts of the territory could not order a plaintiff, in an action for injuries to his person, to submit to a surgical examination in advance of or during the trial of the cause.

The court was asked to overrule the Altizer case, it being suggested that the decision in that case appeared to have been reached because of the binding force on the territorial courts of the doctrine announced in *Union Pac. Co. vs. Botsford*, 141 U. S. 250. But the court says that, while it recognizes that the weight of the state autnorities supports the existence of the power and is against the doctrine announced in the Altizer case, in view of the fact that the rule in that case has stood in this jurisdiction since 1903 and is supported by the decisions of a respectable number of the courts of unquestionably high standing and ability, and in view of the fact that the courts supporting the majority doctrine affirm the existence of the power principally on reasons of necessity, as it seems to them, rather than on judicial precedent under the common law or on the application of recognized principles of common law, the court is not of the opinion that it should overrule the doctrine announced in the Altizer case.

It appears that the existence of the power, independent of statute or of constitutional provision, has been affirmed in Alabama, Arkansas, Indiana, Iowa, Kansas, Kentucky, Michigan, Minnesota, Missouri, North Dakota, Washington and Wisconsin, and has been denied in Illinois, Massachusetts, Texas, New York, Utah, Montana, Oklahoma, and in the federal courts. None of the courts that affirm the existence of the power, so far as this court has been able to examine the authorities, attempts to support its assertion with common-law precedent. Some of them content themselves with the bare assertion of its existence; others strongly reason the necessity of such power to enable the courts to administer full and complete justice and to prevent the practice of frauds in personal injury actions. No case has been called to this court's attention, and none that it has been able to find, satisfactorily accounts for the source of this power, or satisfactorily evolves the doctrine by the application of principles recognized at common law to new conditions.

It is true that, on account of numerous inventions and the important part that complicated and dangerous machinery now plays in the commerce of the world, personal injury actions are more numerous than they were before the establishment of the federal government; but actions for personal injuries existed at common law, and, as has been stated by some of the courts, this power now claimed for the courts does not appear to have ever been exercised by the common-law courts of England, and the fact that no precedent can be found from the English courts supporting its existence is persuasive that no such power existed.

Among those courts asserting the existence of the power, there is a division on questions pertaining to its application. Particularly is this true as to the extent to which the examination may be carried, and as to how obedience to the order for examination may be enforced. By some of these courts it is asserted that anesthetics, drugs and surgical instruments cannot be used in the examination, while in *Atchison, T. & S. F. Ry. Co. vs. Palmore*, 68 Kan. 545, the injection of a drug into an injured eye was held to be authorized. Some of the courts assert that obedience to the order is to be enforced by contempt proceedings, while others hold that failure to obey the order authorizes a dismissal of the plaintiff's action.

This court holds that it is competent, however, on the cross-examination of the plaintiff in the trial of a personal injury action, to ask him whether he is willing to submit to a physical examination of his injuries by a physician, to be appointed by the court or agreed on by the parties. That such question is competent is established in this jurisdiction, and seems to be supported by the decisions of all the courts denying the existence of the power to require an examination in the absence of legislative enactment.

Partner Failing to Use Agreed Business Methods—Sufficient Consideration for Covenant to Refrain from Practice—Case Where Court of Equity Will Not Enjoin from Practicing

(Marvel vs. Jonah (N. J.), 86 Atl. R. 968)

The Court of Chancery of New Jersey holds that under some circumstances a physician may be entitled, for a breach of a partnership contract, to a dissolution of partnership, and an accounting, while the defendant will not be enjoined from practicing in the city. The court says that the complainant in this case entered into a partnership with the defendant and another physician. It was agreed between them that one should render to the bookkeeper, or the person employed for that purpose, a daily account of the work done or visits made that day by him, together with all moneys paid to him on account of the work done or visits made. All professional cards, letter-heads, bill-heads and other stationery relating to the practice generally, were to be furnished by the complainant and were to be used exclusively by the three. The complainant was to have the right to cancel the agreement and oust the party or parties offending, if at any time during the term of the agreement either of the other parties should fail to perform the covenants of the agreement, etc., faithfully, and if either of the other parties should for any reason withdraw from the partnership, or commit a breach or violate any of the covenants of it in such a manner as to justify the complainant in requesting the party or parties so offending to withdraw from the partnership, or to cause the complainant to cancel the agreement, then, in either event, such party or parties should not be permitted to practice medicine in that city for a period of three years next ensuing such voluntary withdrawal or ouster.

This suit was brought by the complainant for an accounting, a dissolution of the partnership, and an injunction restraining the defendant from practicing his profession in the city for a period of three years. The defendant conceded that he had not rendered to the bookkeeper reports of his work in accordance with the requirements of the provisions of the partnership agreement. It was not claimed that he did not fully comply with these requirements of the agreement, and also with the office rules prescribed by the complainant, so far as what was known as "office practice" was concerned. In prescribing for patients during office hours the defendant appeared to have promptly supplied to the bookkeeper all necessary data of his work thus performed. But for what was called "outside work" the defendant during three prolonged periods failed to supply the bookkeeper with a record of his work promptly. No dishonesty or even dishonest purpose on his part was claimed or suggested, and no loss of money appeared to have been occasioned by his negligence in reporting the details of his work during those periods. But his business methods during the three periods referred to were clearly contrary to the terms of the partnership agreement. His excuse for his delinquency in this respect was to the effect that he would become so engrossed in his professional work that he would not find time to make up his accounts for the bookkeeper, and, once falling behind, the task became greater and would not be finally performed until the necessity of settlement required it.

The complainant repeatedly urged him to make prompt reports and he promised to do so, and had, the court is convinced, tried to do so. As the prayer for an accounting and dissolution of the partnership was not resisted, the single question presented was whether the court should exercise its prohibitory power in behalf of the complainant to the end that the covenant of the defendant to refrain from the pursuit of his profession in the city for the period stated might be, in effect, specifically enforced against him.

It was contended in behalf of the defendant that the covenant to refrain from practice was not supported by an adequate consideration. All authorities appear to agree that a valuable consideration must be established to support a covenant of this nature, even though the covenant be under seal, but the weight of authority is clearly to the effect that if a valuable consideration is found to exist the adequacy of that consideration will not be inquired into. The evidence disclosed that when the partnership agreement in question was made the defendant was already a partner of the complainant. The agreement continued their partnership relation under new terms and also admitted to the partnership an additional partner. If the defendant ever understood the terms of his contract — and this was indeed doubtful — the court is fully convinced that until the suit was commenced he was in ignorance of the provisions sought to be enforced. His former defaults of the same nature have been overlooked by the complainant. It was urged by the complainant that the remedy sought flowed by contract from the right of dissolution. That was undoubtedly the language of the contract; but, in administering this form of relief, a court of equity is required to give consideration to a broader view than the naked terms of the agreement, and it thus becomes impossible to ignore the circumstance that the moving and fundamental cause for the relief here sought was the failure of the defendant to render his accounts to the bookkeeper in the manner specified in the agreement, and that this fault, unaccompanied by pecuniary loss or improper motives, and arising chiefly by reason of absorbing devotion to another and more important department of the defendant's partnership duties, could not justly be made the basis of a form of relief in a court of equity which would be fraught with consequences so serious to both the defendant and the public as the remedy here urged.

In considering this remedy as unjust and unnecessarily oppressive under the circumstances of this case, it must be borne in mind that it was more than doubtful whether the pursuit by the defendant of his profession during the period named would result in serious loss to the complainant. That patients would probably be treated by the defendant which might otherwise seek the services of the complainant might be conceded; but the complainant's practice was, in magnitude, far beyond his ability to cope with it without the employment of the services of others, while the consequences which would flow from denying to the defendant the privilege to pursue his practice in the only field of his acquaintance were of the utmost seriousness.

It is not to be inferred from what is here said that relief of the nature here sought is not within the field of equity jurisdiction in cases of this general nature; on the contrary, such relief is not infrequently granted. Nor is it to be here assumed that such damages as the complainant might suffer by the defendant's breach of contract are not recoverable in an action at law. The denial of relief by injunction herein is wholly based on the fact that under all the circumstances of this case the relief sought was unjust and unnecessarily oppressive.

A claim was also made by the complainant that the defendant had violated that part of his partnership agreement which required the exclusive use of stationery furnished by the complainant. That claim was based on the fact that the defendant had not uniformly used prescription blanks so supplied, but had, at times, used blank paper and at other times prescription blanks supplied by druggists on which were printed only the name of the defendant. The court has not been able to regard this alleged breach of the agreement as material.

Surgeon Entitled to Accident Insurance for Loss of Eyesight from Syphilitic Infection from Operation

(*Maryland Casualty Co. of Baltimore vs. Ohle* (Md.), 87 Atl. R. 763)

The Court of Appeals of Maryland affirms a judgment for $7,500 in favor of Dr. Ohle, who brought this action to recover, on an accident insurance policy issued by the company, for the loss of the sight of both eyes caused by having septic matter introduced into his system through a wound suffered in a professional operation. The uncontradicted evidence showed that the plaintiff contracted an infectious disease from a patient while delivering her in childbirth, in the month of October, 1909. He was subsequently treated and attended by experienced physicians and specialists in Baltimore, down to April 4, 1911, when the disease resulted in the loss of sight of both of his eyes caused by blood-poisoning from the wound suffered in the professional operation testified to by the plaintiff.

The court holds that the undisputed facts disclosed by the record brought this case within the terms and meaning of a rider attached to the policy, and covered the claim provided for and the loss insured against in the policy. The language of the rider attached to the policy was clear and unambiguous and must be construed according to the sense and meaning of the terms which were used by the parties making it. By its terms it extended the insurance clause of the policy to physicians or surgeons, and expressly stipulated that the insurance under this policy was extended to cover against death, loss of limb, or sight, total or partial disability caused by blood-poisoning from septic matter introduced into the system through the wounds suffered in professional operations. The object and purpose of the rider was to protect and secure indemnity against total or partial disability caused by blood-poisoning from septic matter introduced into the system through wounds suffered in professional operations.

The policy provided that written notice must be given to the company, or to the agent who countersigned the policy, as soon as might be reasonably possible, of any injury for which a claim was to be made, with full particulars thereof. Affirmative proof of loss of sight must be furnished to the company within two months from the time of loss of sight. "Claims not brought in accordance with these agreements will be forfeited to the company." But that was sufficiently complied with by the notice and statement submitted by the plaintiff to the company on March 14, 1911, which was as follows: "On the seventh of October, 1909, I was attending a woman in labor. I delivered her of a child suffering from syphilis; within two weeks a chancre developed on the middle finger of my right hand. I promptly began treatment, etc.; about April 10, 1910, I developed disease of the eyes, the result of the syphilitic infection. Sight in left eye wholly destroyed, right eye impaired; enter hospital to-morrow, March 15, 1911."

While the accident or injury which resulted in the loss of the plaintiff's eyesight occurred in October, 1909, the proof showed that it was not until March, 1911, that he was satisfied that he would lose the use of his eyes. Manifestly he could not give notice of the loss of eyesight until that condition happened. The words "as soon as may be reasonably possible" as used in accident insurance policies, and relied on by the company to defeat a recovery in this case, have frequently been before the courts for construction, and have been held to mean a reasonable time after the accident occurs, under the facts and circumstances of the particular case.

A View of Medical History.—When we have thoroughly mastered contemporary science, it is time to turn to past science; nothing fortifies the judgment more than this comparative study; impartiality of mind is developed thereby, the uncertainties of any system become manifest. The authority of facts is there confirmed, and we discover in the whole picture a philosophic teaching which is in itself a lesson; in other words, we learn to know, to understand and to judge.—Littré, Œuvres d'Hippocrate, i. 477.

Society Proceedings

CHICAGO NEUROLOGICAL SOCIETY AND THE BIOLOGICAL CLUB OF CHICAGO

Joint Meeting, held Dec. 18, 1913

The President of the Chicago Neurological Society, Dr. Ralph C. Hamill, in the Chair

Demonstration of Lange's Colloidal Gold Test in the Spinal Fluid

Dr. A. M. Moody: This test I believe to be the most valuable, especially from the point of view of diagnosis. Lange's technic is as follows: A series of ten test-tubes is used, 6 by ¾ inch in size. In the first, place 1.8 c.c. of a 0.4 per cent. sodium chlorid solution, freshly made from a stock 10 per cent. solution, in one test-tube, and 1 c.c. in each of the other nine. Then take 0.2 c.c. of yeast and add to the first two. This is mixed with a 1 c.c. pipet. One c.c. is removed and added to the second tube, making a dilution in this tube of 1:20. This procedure is carried on throughout the series. When finished, there is 1 c.c. in each tube, varying from 1:10, 1:20, 1:40, and so on up to 1:5,120 in the last tube. It is the making of the indicator that requires the greatest care. Absolute chemical cleanliness and the following of the technic in detail is the only possible way to obtain the best indicator. A good indicator is necessary for accurate results. When good, it is absolutely clear red, with some yellow and a tinge of purple.

The tests should stand for twenty-four hours that the maximum reaction may be secured before the final reading is taken; nevertheless, within from fifteen to thirty minutes one can tell what the result will be. In order to facilitate the reading and interpretation of the results, we may divide the reaction into three groups: (1) the reactions which are strongest in dilutions of 1:40 and 1:80; (2) those having the maximum reaction in dilutions of 1:80, 1:160 and 1:1,320; (3) those reactions which are strongest in dilutions of 1:640 up to 1:5,120. Diseases of the brain and cord falling into the first class are those due to syphilis, namely, syphilitic meningitis, gumma of the brain, tabes dorsalis, general paresis and congenital syphilis. Tuberculous meningitis usually gives the strongest reaction. Brain tumor, toxic meningitis and edema from sunstroke may give a slight reaction of equal intensity.

In my work the Lange reaction runs parallel with the Nonne. It bears relationship to the Wassermann reaction—this is so constant that in a series of over three hundred cases one can predict from the Lange test, the outcome from the Wassermann reaction. It seems fair to say that from the small amount of spinal fluid used—0.2 c.c.—and the ease and rapidity with which one may come to definite conclusions, it is the most valuable of our present-day laboratory methods for the examination of the spinal fluid. This is true not only in pathologic spinal fluids during life, but also in confirming anatomic changes found at necropsy.

DISCUSSION

Dr. Peter Bassoe: When I first heard of this test, it did not seem to me that it could really have any definite relation to pathologic conditions, but I soon became convinced that it really was so, partly by having the test made on all of the spinal fluids from patients with whom I was acquainted, and partly because I soon saw that with a very little practice I could make a good guess at the clinical diagnosis. One of my first experiences was with a case that had baffled me for about three years clinically. The man was what we would call neurasthenic, but had some transitory speech disturbance, which led me to be suspicious of paretic dementia; but he gave a negative Wassermann test. Finally I tried the spinal fluid and it gave a weak Wassermann test, while the blood was still negative. The Lange test was of the typical type, nevertheless. Similarly, in the cases that gave a reaction characteristic of cerebrospinal syphilis and tabes the results seemed convincing. I had an obscure case in a patient who first had pyorrhea then suddenly became severely ill with high fever, and developed an analgesia of the face on the right side, and a partial paralysis and sensory disturbances on the left side—in other words, a pons lesion. He improved but after a while had another attack, and after this attack he remained paralyzed. The Wassermann test was negative. The spinal fluid showed a reaction rather weaker, but of the same type as we see in the meningitis and the brain abscess cases. That patient finally came to necropsy and what appeared to be a simple encephalitis was found. There was no sign of syphilis in the body. I do not believe that Dr. Moody has had occasion to examine the spinal fluid in typical multiple sclerosis. It might be interesting to try it.

One word in regard to the globulin test. Dr. Moody uses the Nonne test. I agree with him that it is a much cleaner test. But still more satisfactory and easier to read is another test with ammonium sulphate, which amounts to the same thing—the Ross-Jones test. It is simply a contact test; instead of mixing the spinal fluid and ammonia solution at once, the spinal fluid is allowed to float on top of the ammonium sulphate solution. I make that first, wait a minute or so, then shake it up, and if there still remains a distinct cloud, I make the two tests at the same time.

Dr. C. G. Grulee: My work has been in regard to congenital syphilis. I had reason for thinking that a great many cases of congenital syphilis went undiagnosed if we depended only on the Wassermann test for the diagnosis. The test has helped me a great deal in distinguishing cases of congenital syphilis, and I think that if we rely on it tentatively, with the proper restrictions, we can feel that it is a very good test for confirming a diagnosis of congenital syphilis. I should not base a diagnosis on it alone, but I do think that, other things taken into consideration, it is a strong factor in favor of congenital syphilis, when positive.

Dr. Julius Grinker: I was in Berlin when Dr. Lange organized a class for giving instruction in making this test. I was unable to secure entrance to this class, but questioned some of the men, and also procured a very complete monograph which had just been published by Lange. I asked these men if they could make a positive diagnosis of general paresis and cerebrospinal syphilis, and they said that Lange did not tell them that. Lange said that the test was merely confirmatory, and it still needs a great deal of work to make it a positive and infallible test. So I came to the conclusion that the Lange test is no better than the Nonne test; it teaches no more than the Nonne test, if properly performed, and, as you know, the Nonne test itself will not make the diagnosis for you. You have to make it and merely apply the test to confirm it. Before this colloidal test can become popular and the common property of the profession, it will have to be simplified considerably. Therefore it seems to me that while we want to know all about it, and while it is something of great value, yet the test itself is not one that we can depend on solely to make our diagnosis. I believe that we shall have to keep the Wassermann, Nonne and Noguchi tests for a long time yet before we find something to replace them.

Dr. Arthur F. Beifeld: Has Dr. Moody any statistics on the gold colloidal reaction in disease other than tabes, general paresis or cerebrospinal syphilis?

Dr. D'Orsay Hecht: Does Dr. Moody think that the presence of blood, if only infinitesimal in amount, completely invalidates the test? Dr. Grinker is right in emphasizing the fallibility of this test, but this is true of all tests. For a clinician to assume that he is in a position to make a diagnosis from a laboratory test alone is taking altogether too much for granted. Laboratory tests should be confirmatory.

Dr. W. S. Timblin: During the last month in the Michael Reese Hospital we have made ten or more tests. Two of the cases were clinically general paresis and three tabes. The matter of making up the indicator does not present the great difficulty that some men have been led to believe. It really takes neither much trouble nor much time. With us the test has been extremely striking in the limited number of cases at our disposal.

Dr. A. M. Moody: I have not the statistics at hand now, but expect shortly to prepare a paper comparing the spinal fluid tests, and the relations between the Wassermann reaction and post-mortem fluids, including serum and spinal fluid. I have tried the gold chlorid reaction in cases other than syphilis. I have had a few cases of suppurative meningitis. All those cases in which I did find a reaction for syphilis were cases in which there were typical lesions of syphilis of the meninges or within the brain. The presence of blood in the spinal fluid, if it is a tabes or a general paresis—even the presence of a few corpuscles seen in the bottom of the tube—will modify the test a very little. If there is any marked amount of blood in the spinal fluid, then we should not rely on the result of the Lange test. Blood in the spinal fluid spoils it for practically all tests, excepting, perhaps, the cell-count.

I did not mean to leave the impression that this test was infallible. Lange has recently reported one thousand cases of spinal fluid examinations which were paralleled by the Wassermann reaction, and the reason that he has obtained higher results than any one else is that he uses a greater amount of spinal fluid. He uses 5, 10 and 15 c.c. of spinal fluid sometimes to secure a positive reaction, and in this article he states that as high as 30 c.c. of normal spinal fluid can be used, and the Wassermann remain negative. The test is of value only as a confirmatory test, when the other tests are taken into consideration, as well as the clinical diagnosis, but it does differentiate different groups of diseases.

(To be continued)

WESTERN SURGICAL ASSOCIATION

Twenty-Third Annual Meeting, held at St. Louis, Dec. 19 and 20, 1913

The President, Dr. Jabez N. Jackson, Kansas City, Mo., in the Chair

Tuberculous Hip-Joint Disease and Its Treatment with Bismuth Paste

Dr. Emil G. Beck, Chicago: Hip-joint disease in its incipient stage is too frequently diagnosed as rheumatism. Two-thirds of the patients give the history of having been treated in the beginning for rheumatism or sciatica. When the disease has progressed to the stage of abscess formation incision and drainage, as a rule, has been the form of treatment, a method which is now generally condemned. Sacral tuberculosis or that of the sacro-iliac joint is frequently mistaken for hip-joint disease. I have seen five such cases. This mistake is explained by the similarity of the swelling and contractures of the limb on the affected side. A patient who for years could not carry his weight on diseased limbs on account of acute pain in the joint, and was obliged to use crutches, could, after the joint was closed, walk without pain, and in most instances the patient was allowed to discard the crutches.

The prevention of bismuth poisoning consists in not allowing large quantities of the paste to remain in the body for absorption. Should the symptoms appear, the paste must be removed by washing out the cavity with warm olive-oil. The sterile oil is injected and retained for from twelve to twenty-four hours in order to produce an emulsion, which should be withdrawn by means of suction. After its removal all symptoms will promptly disappear. Scraping out the paste with a scoop is a dangerous procedure because it opens fresh channels for absorption.

DISCUSSION

Dr. J. W. Cokenower, Des Moines, Iowa: I tried phenol (carbolic acid), formaldehyd, iodoform, etc., as injections, and failed. I tried bismuth paste and failed. Bismuth poisoning also occurred. The reason was that in a case of cold abscess I made too large an incision. There seemed to be considerable necrotic tissue. In curetting I exposed new tissue and injected the paste; in the place where I left it raw the paste was absorbed. To obviate my mistake, I injected olive-oil, filled the wound solid, allowed it to remain twenty-four hours, then pumped out the paste and saved the patient.

One should make a small incision in these cases, the pus being sterile, and inject with bismuth paste; the presence of the paste will stimulate leukocytosis and proliferation of tissue. If the injection has been made properly, one injection is sufficient.

Dr. Emil G. Beck, Chicago: I think that leukocytosis is the underlying factor, and this is probably caused by bismuth subnitrate. I do not think that it is absolutely essential to use bismuth. Other substances may do, but so far I have found no good substitute. I have tried ten or fifteen substances, but none has proved satisfactory.

Use of the Wire Clamp in Operations for Goiter

Dr. Leonard Freeman, Denver: The wire clamp has a number of advantages: 1. It may be adjusted to almost any goiter, by bending the wires if required, although this is seldom necessary. 2. The control of hemorrhage nearly always is perfect, so that the gland may be sliced off beyond the clamp with absolute confidence. 3. The tissues are not crushed, but simply constricted as in the use of a tourniquet, which is of importance in exophthalmic goiter, at least. 4. There is no danger to the recurrent laryngeal nerves or to the parathyroids. Even if they should be caught in the grasp of the wires, which is unlikely, the compression would not be great enough to do them permanent injury. 5. There is no chance of the wires slipping from the stump after the gland is resected, because they are held in place by the loops passing through the base of the lobe. 6. The wires are much narrower than the blades of a pair of forceps and hence take up less room. I have used this method in twenty goiters of various kinds in which it seemed to be indicated. The operations proceeded easily, safely, without anxiety, and there were no fatalities.

Parosteal Callus: The So-Called Myositis Ossificans Traumatica

Dr. Oliver J. Fay, Des Moines, Iowa: I have seen six cases of traumatic intramuscular ossification; in four the brachialis anticus was the muscle involved, in two the vastus medius. In two cases the ossification followed a dislocation of the elbow, in three others a contusion was the determining factor, while in the remaining case there had probably been a rupture of the muscle. The youngest patient was 16, the oldest 50.

None of the four theories advanced to explain the pathogenesis of these intramuscular bone formations (the hemic theory, the theory of aberrant sesamoid bones, the theory of periosteal detachment or dissemination, and the theory of ossifying myositis) is entirely satisfactory. The first two have found but few supporters; the third does not explain muscle ossification in muscles not overlying the bone, while the fourth, so far as it assumes a hematogenous infection, lacks clinical evidence. Histologically, the bone mass is found to bear a close resemblance to the callus of fractures; the whole picture is that of a reparative process, the damaged connective tissue-cells having temporarily lost their differential function and become osteogenetic. Since the term "myositis ossificans traumatica" emphasizes the inflammatory rather than the reparative nature of the ossification, I prefer the appellation "parosteal callus."

The early symptoms are those of any contusion, but the functional does not keep pace with the objective improvement and an indurated mass becomes palpable. The roentgenogram is essential to differential diagnosis. Operation is indicated when there is functional disability or when the parosteal callus interferes with the blood- or nerve-supply. The prognosis is good unless there is periarticular ossification. An early operation must be radical and all damaged tissue removed to guard against a recurrence, but better functional results are obtained if the callus is allowed to "ripen." A conservative operation is then possible and the maximum amount of the muscle-tissue is saved.

Multiple Exostoses: A Hereditary Affection of the Bony Skeleton

Dr. Roger T. Vaughan, Chicago: All cartilaginous exostoses are congenital in origin, being demonstrable probably at birth, though usually not recognized by patients or clinicians till years later. The tendency to their formation is hereditary and transmissible. They are frequently accompanied by other developmental defects of the skeleton, some of which are characteristic of the affection. These tumors may be accompanied by congenital defects of other body structures.

Multiple cartilaginous exostoses, as a rule, are a harmless affection. The disturbances in the wrist- and elbow-joints are the most bothersome. On account of their location a few exostoses may become very burdensome, but they are rarely dangerous. Those exostoses which lock the joints may be removed. Neuralgia, paralysis, epilepsy, apoplexy, defective hearing, dystocia in labor and rupture of the uterus, exophthalmos, rupture of the popliteal artery with aneurysm formation, and also malignant degeneration have been described. In view of these severe, even if infrequent, complications and the considerable and not infrequent deformities occurring in this disease, the undesirability of the intermarriage of members of exostosis families in the light of Mendel's law should be recognized by physicians and eugenists.

DISCUSSION

Dr. A. A. Law, Minneapolis: We recently found in the Minnesota clinic that it is an absolute impossibility to differentiate these benign conditions in some cases from the extremely malignant osteosarcoma, with a mortality of practically 99 per cent. from metastases. A case in point prompts me to bring up this question. A boy in a football accident was kicked above the left patella. A month after the accident he had a typical fusiform, noninflammatory tumor, apparently in connection with or attached to the femur. Twenty roentgenograms were taken of the femur. We could not make the differentiation for the reason that the picture presented by the roentgenogram was that of osteosarcoma with feathery trabeculae about the femur. Exploration was finally resorted to, and the tumor was found to be inflammatory. There was a degenerating blood-clot.

Dr. Arthur E. Hertzler, Kansas City, Mo.: If we bear in mind that the ray-like processes in ossifying myositis run parallel to the fascia and muscle fibers, while in periosteal sarcoma the rays are fan-like, extending from the base of the bone in all directions, and not parallel to the muscle fibers, it will assist in the differentiation.

Dr. Emil G. Beck, Chicago: I have taken different bones and made stereoscopic pictures of them, and through the stereoscope we obtain very fine points, the three dimensions and the changes which on a single plate are very diffuse become concentrated. We can differentiate a sarcoma from a cyst or inflammatory condition by stereoscopic pictures.

Dr. M. L. Harris, Chicago: There are two other varieties of the so-called ossifying myositis. The traumatic variety develops at the point at which the muscle has a broad attachment to the bone, where there is no periosteum which can play a part in the process. It is very important in the diagnosis of osteosarcoma to remember that this condition never has a distinct, individual growth like a tumor. The growth is always limited, and when once the foundation is laid, never shows a progressive tendency. The original outline is seen in the early roentgenograms and appears to enlarge on successive plates.

Dr. D. S. Fairchild, Des Moines, Iowa: A boy, aged 20, received an injury to the elbow-joint. The nature of the injury was not known. The case had been treated as a fracture and the elbow-joint was kept in splints for some time. The patient was sent to a doctor in our community; roentgenogram was made, and the doctor proposed that something should be done at once to secure good motion in the elbow-joint. He operated but the result was not satisfactory. The patient came to me. I made the roentgenograms and found the conditions described by Dr. Fay.

Dr. James F. Percy, Galesburg, Ill.: I operated on a woman, now 45 years of age, about ten years ago for an extensive carcinoma of the right breast. She had no signs of recurrence for eight years, and then she returned with pain above the collar-bone and extensive swelling of the right arm. Examination showed that the subclavian vessels were probably being pressed on by this growth, and the skiagram revealed a growth springing from the fourth or fifth dorsal vertebrae, going up back of the lung and coming up inside of the collar-bone. I assumed that this was a recurrence in the bone of carcinoma. She has had in the neighborhood of 230 Roentgen-ray treatments. At present there is almost nothing to be seen of this growth.

Gas Bacillus Infection

Dr. W. D. Haines, Cincinnati: The intestinal tract is one of the normal habitats of the gas bacillus, and invasion of the adjacent cellular structures may take place through ulcer, malignant disease or perforation. An enormous abdominal distention from gas bacillus has been mistaken for postoperative dilatation of the stomach. In one case of infection of the scrotum and one of the arm, recovery followed free incision.

The *Bacillus aerogenes capsulatus* is anaerobic; therefore, success in the treatment will depend more on free exposure of the infected area than on any form of local or internal medication.

Fee-Splitting

Dr. Jabez N. Jackson, Kansas City, Mo.: This is a practice which leads to several indictments. It induces family physicians to betray the sacred confidences of their trusting patients and refer them not to those men who are most competent and who offer the greatest possibility of the saving of life and the preservation of health, but to men who pay for the victim. It lowers the dignity and value of the services of the family physician, who is presumably rendering valued services for nothing, and gives a magnified value to surgery, which is presumably receiving all. How much more exalted would be the standing of the general practitioner if people were taught to value his services in diagnosis and his responsibility in counseling surgery and recommending a surgeon and that they should pay for this service as they would for any other. It should be the privilege of the surgeon to aid the physician openly to secure this just compensation. As a rule the patient is robbed, paying two fees instead of one, as he supposes. Fee-splitting is the stepping-stone by which incompetent men secure business. It penalizes honesty in the young surgeon who is capable but must sit idly by and starve while his less competent competitor buys the business. It leads to many unnecessary operations with their attendant risk and expense performed merely because the patient can be induced to submit and has the price. It is a betrayal of trust, encourages dishonesty, breeds incompetency and should, in short, be held a crime.

(To be continued)

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION

Twenty-Sixth Annual Meeting held at Atlanta, Ga., Dec. 16-18, 1913

The President, **Dr. John Young Brown**, St. Louis, in the Chair

Successful Suture of Stab-Wound in Right Ventricle of Heart

Dr. Joseph Danna, New Orleans: I removed the third, fourth and fifth costal cartilages and made a free incision of the pericardium, exposing the heart to full view. Manipulation of the heart was not attended with either shock or pain; the patient talked and felt comfortable during the process of suturing, sponging, etc. The heart can be steadied by forceps or sutures without harm. The placing of the sutures through and through did no harm in this case, although authorities advise not letting the sutures penetrate the endocardium. The pericardium was not drained, although this is also advised. The pleura was opened in getting the proper exposure, an accident which usually happens in these cases, but which I believe might have been avoided with care. In every case of wound of the chest, with signs of severe hemorrhage, in which the bleeding is believed to be the result of injury to the intercostal arteries, internal mammary artery or the heart or its coverings, operation should be performed. No case should be considered too far advanced for operation. If this is done a life will occasionally be saved.

Direct Suture of the Brachial Artery for Traumatism

Dr. J. Garland Sherrill, Louisville, Ky., reported a case of direct suture of the artery for traumatism, with restoration of the circulation, but with the subsequent development of ischemic paralysis.

Surgical Repair of Blood-Vessels

Dr. J. Shelton Horsley, Richmond, Va.: Blood-vessel surgery has four fruitful fields: (1) trauma of the vessels; (2) malignant growths that involve the blood-vessels; (3) aneurysms, and (4) transfusion of blood. In suturing vessels the same principle of approximating endothelium obtains as in suturing intestines—only the endothelium is on the *inside* of the vessel while on the *outside* of the bowel. So in suturing vessels a flange must be turned *out*, just as in suturing intestines it must be turned *in*. [Dr. Horsley then described his special technic of suturing blood-vessels.]

DISCUSSION

Dr. R. H. Hill, Montgomery, Ala.: I saw a case of a needle stuck in the heart of a little girl. The needle was removed under local anesthesia. The external end of the needle could be seen plainly under the skin with each movement of the aorta. In another case I assisted in removing the piece of a hatpin from the heart of a negro man. A man suffered no special inconvenience although his pulse was irregular as long as he occupied the upright position; but when he undertook to lie down he had considerable pain and great difficulty in breathing. The foreign body was removed by a modified Rotter operation. I also assisted in suturing the heart of a boy who was stabbed with a penknife.

Dr. Walter C. G. Kirchner, St. Louis: I have seen five cases of heart-suture and have operated in two myself. One of the patients on whom I operated recovered. It is important for the surgeon who is likely to have emergency work of this kind to have a definite plan of operation and a definite means of opening the chest, so that it can be opened quickly and without much confusion. Deep anesthesia is dangerous because when the chest is opened the lung does not work so well as when the patient is partially anesthetized. So it is better to use light general anesthesia or local anesthesia. The danger of pneumothorax has been overestimated.

Dr. Herman J. Boldt, New York: I should like to suggest that rectal anesthesia might well be substituted for general anesthesia in these cases.

Dr. Francis Reeder, St. Louis: The suture which I have employed is that, in place of the mattress-suture parallel with the plane of the intestine, I have taken the mattress-suture and placed it vertical to the axis of the vessel.

Dr. I. R. Stone, Washington, D. C.: I should like to ask Dr. Sherrill how much usefulness of the arm was preserved in the case he reported.

Dr. J. G. Sherrill: The patient had considerable power in carrying things on the forearm. He has some prehensile ability and can pick up things to a small degree with the fingers, but the result is not so satisfactory as I had hoped to obtain.

AMERICAN ASSOCIATION FOR STUDY AND PREVENTION OF INFANT MORTALITY

Fourth Annual Meeting, held in Washington, D. C., Nov. 14-17, 1913

(*Continued from page 66*)

The Ideal Obstetric Outpatient Clinic

Dr. Franklin S. Newell, Boston: Factors necessary for the establishment of such a clinic are: (1) a considerable class in the community who require free or practically free care; (2) an adequate supply of medical students who can provide such care under the supervision of a well-trained obstetrician, and (3) a well-equipped hospital in which all serious obstetric abnormalities can be cared for. The work of the outpatient clinic should be divided into three departments: prenatal care, the care of labor, and after-care.

Prenatal care should include (1) instruction in the hygiene of pregnancy; (2) repeated examination to determine the presence of abnormalities, and (3) visits at the patient's home to supplement the work of the clinic. Only patients believed to be normal should be cared for in the outpatient clinic. Abnormal cases should be referred to the hospital for care.

At the time of labor the patient should be instructed to apply to the outpatient station for a doctor at any time, night or day, as soon as labor begins. The work of the students in the outpatient clinic should be carefully supervised by a house officer attached to the clinic who is under the charge of a properly trained obstetrician. Definite rules should require that the student report to the house officer the progress on any case on which he is in attendance at given intervals. The student should be given as much responsibility in each case as is consistent with the well-being of the patient.

The after-cure of each patient should preferably be conducted by the student who has delivered the patient, supplemented by a nurse attached to the clinic, and the work of the student checked up by the house officer at definite intervals. No patient should be discharged from the clinic without being certified as being obstetrically well after a complete physicial examination by the house officer. In order to insure the best results each patient on discharge should be referred to the pediatric clinic for advice in the proper care of her infant. The expense of maintaining such an outpatient clinic is not prohibitive. Such a clinic can be made practically self-supporting by voluntary subscriptions by the patients, if the patients receive adequate care.

DISCUSSION

Dr. J. Whitridge Williams, Baltimore: I agree with Dr. Newell's conclusions, but think that the work should be organized along somewhat broader lines. It should include consideration of (*a*) the best method of caring for all women who need it; (*b*) the effect on the community; (*c*) its bearing on the education of medical students, and (*d*) its effect on advancing knowledge. In large cities the work is too extensive and diffused to be undertaken by one clinic and should be undertaken jointly by the city and the hospitals with the necessary number of substations. All women whose husbands have less than a certain minimum yearly income should be eligible for such care. The very poor should receive it gratis, while a second class should pay a small fee. To prevent abuse, cooperation with social service workers is essential, which might well be combined with the prenatal care. The community would benefit by having fewer invalid women, more well babies and no blind ones. The city would save money for the reason that it would be necessary to support fewer women in hospitals while being treated for avoidable consequences of childbirth. The midwife problem would eventually be solved.

The medical student should be trained to become a better and safer physician. The entire scheme would fail to produce the best results unless its direction were in the hands of broad-minded men, who are interested not only in caring for the women and their babies, but in actually advancing knowledge. One method would merely substitute male for female midwives, while the other would train a certain number of persons to be scientific obstetricians and productive investigators. This means that men with university ideals must be in charge of the work.

Dr. S. Josephine Baker, New York: I endorse any movement which will make for better care of mothers and babies in our large cities. There is a tendency in most of our city governments to assume more and more the attitude of so-called paternalism in regard to child-welfare movements, and it is possible that such a movement as this may come into being. When it does, it will do a great deal to solve our vexed midwife question and the question of the poorly prepared doctor, which is a very serious one in our big city; and it will help to solve the problem of the deaths from congenital debility. Unless we can reduce those, we cannot make much more of a reduction in infant mortality, particularly in those places where much work has been done in the last few years. On that account movements of this sort are attracting a great deal of attention to the desirability of prenatal care of pregnant women.

Dr. Gavin Fulton, Louisville, Ky.: For five years we have tried to establish an outpatient clinic in Louisville in connection with our child-welfare work. We think that prenatal care and proper obstetric care of the mothers are the most important phase of our work. We have finally made a start with a weekly clinic, for those who are able to pay as well as for the very poor. The dean of the medical school has made it financially possible for us to hire two small rooms, and the Babies' Milk Fund Association furnishes a nurse. The university sends us two students at a time, each of whom serves one month. We are trying to give each student ten cases.

Use of Vital Statistics in Preserving Infant Life

Dr. W. C. Woodward, Washington, D. C.: I wish to emphasize the utilization of vital statistics as a method of determining the extent of infant mortality, the direction that efforts should take to limit such mortality, and the efficiency of such efforts. This not only requires the utilization of existing systems of mortality and morbidity statistics so far as they relate to the ordinary communicable diseases, but requires an extension of the ordinary morbidity statistics so as to cover infantile diarrhea and possibly other diseases of infant life, even though such diseases are not recognized as communicable. In order to determine the direction that efforts toward the limitation of infant mortality must take, it will be necessary to have, in addition to morbidity and mortality statistics, certain sociologic statistics bearing on the ability of the parents to care for their offspring properly and on local sanitary conditions for which the city or state is responsible. These several groups of statistics, properly collated and analyzed, would undoubtedly promote efficiency and economy in the expenditure of effort and money for the prevention of infant mortality, and are essential to any rational effort along such lines.

DISCUSSION

Dr. S. Josephine Baker, New York: The birth-record is the starting-point of about 75 per cent. of our effective baby-saving work. Vital statistics are of value only so far as they are used. The use of the birth-certificate is mainly that of effectively reaching the mother as soon as possible after the baby is born. The great majority of babies who die during the first month could be saved if we could reach the mothers early. To be effective our registration should be made within forty-eight hours after the birth. Using the birth returns as they come in, it is possible to send a visiting nurse at once to see the mother and put her in touch with the various agencies which may be of service to her. Morbidity statistics are in many instances of such doubtful value that my experience has led me to be skeptical of them. I had occasion within the last few years to discount almost entirely the value of the analysis we make of various classes of disease causing death. Our returns on one occasion *showed a terrifying* increase in diarrheal mortality. The total number of deaths of infants was not any larger than it had been for the same period for the year before. A great decrease was noted in the deaths from congenital causes, and a marked increase in the deaths from diarrheal diseases. When we divided our mortality into that from institutions and dwellings, we found that this excessive increase was in one institution, a foundling asylum. A conference was held and one of the physicians of that institution said he could reduce that in fifteen minutes. He had read the book of the federal census bureau which said that malnutrition should not be accepted as a cause of death.

Dr. L. Emmett Holt, New York: Too many statistics are circulated that have for their main purpose inducing people to contribute to the support of some undertaking. I have in mind the report of an association as it is issued every week in New York. It gives the number of milk stations in operation and the number of children saved, the mortality among the children coming to the station being about 0.5 per cent. of the mortality of children treated in institutions. The conclusion to be drawn from these statistics is that the only way in which children can be saved is by going to that milk station. During the last year we have had a large proportion of intestinal cases referred to us from the milk stations. A large proportion of the patients died within twenty-four hours after they were referred. The inference is that the milk station keeps the children under observation until they see they are going to die and then turns them in to the institution to the discredit of the institution. One milk station published a report of serving 5,000 children with only one death in a month. That is absurd. It is dishonest. It leads one to distrust figures and hurts the cause of vital statistics.

Dr. Philip Van Ingen, New York: For the first time in the history of this country we have figures from widely scattered areas on mortality by age groups. In studying these one thing has been brought strongly home to me, and that is the necessity of uniform methods of tabulation. In Memphis you will find that while they had 350 deaths in one year, they had approximately between 30 and 32 per cent. under a month of which they had no records. I presume that they were tabulated as stillbirths and thrown out of the death records.

Mr. Lewis Meriam, Washington, D. C.: The federal children's bureau has been trying hard to make the subject of birth registration popular to the laity, and especially to the women of the country. Our method is to write to the state presidents of various women's organizations and get them to interest their members.

Mrs. William Lowell Putnam, Boston: The registration of still-births is a very important matter, and one which is very much overlooked. If the still-births were correctly reported and registered and counted as still-births, I cannot but feel it would have more to do than anything else in bringing before the public the importance of prenatal care. We have been doing this work for four and a half years. For the last two years we have found still-births to be 18.6 per thousand. In the city of Boston they have been 39.3 for the last year and 39.9 for the year before. We have also been able to reduce the percentage of premature births. Last year we had only 0.4 per cent. of premature births, and we feel that that must redound toward the health of the children.

7. **Nerve Supply to Hypophysis Cerebri.**—According to Dandy, the nerve supply to the pituitary body is from the carotid plexus of the sympathetic system. Numerous branches radiate to the stalk along the hypophyseal vessels and are immediately lost to view in the substance of the anterior lobe. The posterior lobe nerve supply is very scant, in marked contrast to the extensive innervation of the anterior lobe. The pars intermedia receives its nerves from the stalk. There is connection between the carotid sympathetic system and the oculomotor and optic nerves. The absolute differentiation between secretory and vasomotor nerves is, Dandy says, a matter of much dispute and is impossible. The impression, however, from the character and course of the nerve fibers, their greatly increased number in the region of the hypophysis, and their disappearance at a distance from the hypophysis, the differences between the supply of the anterior and posterior lobes, the connection established with the other cranial nerves, lead us to regard them as secretory, in contradistinc-

tion to vasomotor, the existence of which in the cranial chamber has not been observed.

8. **Morphogenesis of Mammalian Ovary.**—Sixty cat ovaries were studied by Kingsbury. The results of his investigations may be stated as follows: In the development of the ovary of a cat, growth is mainly peripheral and marginal. Differentiation therefore follows centrifugally. The epithelial elements (parenchyma) occur in the form of cords. Medullary cords and egg cords are not to be sharply distinguished. The growth determines the appearance of fairly definite zones: (*a*) cortical, (*b*) intermediate, (*c*) epithelial stromal. Degenerations occur throughout the period of growth and in the adult period. In general, the degenerations follow a centrifugal course. The stroma obviously plays an active and important part in ovarian growth. The primitive cortex is interpreted as directly forming the definitive cortex containing the primary follicles. No evidence was found of a new formation of ova just prior to sexual maturity. Profound degeneration of the early formed Graafian follicles occurs, being most marked before the advent of sexual maturity. Polar spindles, polar body formation and fragmentation (abnormal cleavage?) occur particularly in the atresia folliculi preceding sexual maturity. The Graafian follicles of the adult period are of a somewhat different type as compared with those of the growth period (presexual). Intergradation is, however, obvious.

15. **Urine Examinations.**—There is no doubt in Muhlberg's mind that diabetes is increasing in prevalence and he attributes this partly to the increased nervous stress of modern life and partly to the tendency toward over-eating and lack of exercise. The death-rate from this affection has gradually crept up from the year 1900, during which year the deaths are represented on a 100 per cent. basis, to 142 per cent. during the year 1909. And this has occurred in spite of the earlier recognition, the marked results from improved therapeusis and gradual unfolding of the true pathology of this affection through the splendid researches of pathologists and clinicians. Like arteriosclerosis, diabetes seems to be making its ravages among the better element of the population and therefore is particularly noticeable among insurance risks. Sugar is found in a greater percentage of samples at present than six or seven years ago. Muhlberg employs the Fehling method recommended by Dr. Ogden and in his opinion it is the best.

He concludes as follows on this topic:

> In spite, however, of our careful instructions, we find that even our best examiners will fail to detect sugar in urine containing less than ½ per cent. and the difficulty arises from imperfect technic and the confidence that most examiners have that the operation is too simple to admit of mistakes. It must be confessed that the detection of small amounts of sugar varying from 1/10 to 1/4 per cent. is not easy, especially since concentrated normal urine, sugar free, will at times show a reduction of Fehling's equivalent to 1/4 per cent. of sugar. We have practically discarded the phenyl hydrazin test as a check against our Fehling's. For some reason or other—and this observation is not at all original—phenyl hydrazin will occasionally fail to precipitate the typical osazone crystals even where pathological amounts of sugar are present. In our experience, the osazone compound is probably formed but fails to crystallize and the absence of the typical crystals leaves one in doubt. Instead, we are using the fermentation test. It, too, has its shortcomings, inasmuch as the degree of acidity of the urine and the presence of sugar in the yeast itself slightly influence the findings. But we have found that it is sufficiently delicate—less than 1/10 per cent. can readily be detected thereby.

17. **Bacterial Vaccines in Pneumonia.**—The best method of procedure, in Craig's experience, is to administer a polyvalent stock vaccine of the pneumococcus and streptococcus, of each thirty million, at as early a date as possible. Make sputum smears and cultures, blood cultures in early cases, lung puncture in late ones, and proceed to the preparation of an autogenous vaccine. If there is no definite response in 24 or 48 hours, repeat or preferably give an autogenous vaccine. If there is no response in 36 or 48 hours, double the dose. If there is a response, as evidenced by improved clinical symptoms and signs, increased well-being of the patient, etc., defer reinoculation three days or until the first symptoms of retrogression in the general condition or the physical signs occur. Maintain the dosage or increase it every two or three days until the patient is entirely well. Generally about three doses are necessary.

Craig has found them to be an improvement on all other methods of treatment. Vaccine treatment, properly carried out, is capable only of good. Hundreds of cases have been reported with an average mortality of 5 to 10 per cent. The mortality from the old routine treatment is still 16 to 20 per cent. and in alcoholic cases, nearly 50 per cent. in some epidemics. In twenty consecutive cases, seen by Craig in private practice, there was but one death. In hospital practice as a rule, the cases are not seen early enough.

In considerably over a hundred patients treated, Craig has observed that the disease runs a shorter course, the patients are less toxic, there is less fever, and generally no delirium occurs except in alcoholic cases. Convalescence also is shortened and the danger of complications is lessened. Best of all, more of the patients get well.

19. **Progeny of Tubercle Bacillus.**—Mixed infection in tuberculous areas, in Maher's opinion, is caused, not by the invading of these areas by bacteria from the outside, but by the development in these areas of the bacterial progeny of the struggling tubercle bacillus. He explains this as follows: Old tubercle bacilli alive in a moist, somewhat, unfavorable environment, swell or elongate and become markedly granular, lose more or less of their acid-fast resistance, and fuse together into a poorly acid-fast granular or homogeneous matrix. Subcultures from this matrix on various media not quite suitable for tubercle bacilli develop poorly acid-fast or non-acid-fast bacilli or cocci, which have no longer the power of causing tuberculosis in injected animals, but have the power of increasing the virulence of simultaneously injected tubercle bacilli.

From this matrix of fused old tubercle bacilli can be developed bacterial forms similar to Much's coccal granules, Foulerton's streptothrical forms, Dixon's branching forms, and Ferran's rod forms. From this matrix it is possible to grow coccal and bacillary forms that vary in morphology, in acid resistance, and in chromogenic power, according to the variance in the age and vegetative energy of the tubercle bacilli that composed the matrix, and according to the variance in the technic to which the matrix is subjected. All of these derivatives of tubercle bacilli are very tender. They need constant watching. Many of the first sub-cultures die without apparent reason. They are very sensitive to environment. After they have grown for a few generations at 37 C., or at room temperature, they will not grow well at any other. In sub-cultures they all grow best on glycerinized media.

All non-acid-fast coccal and bacillary derivatives of the tubercle bacillus are Gram-negative. One of the most striking and suggestive methods of developing the non-acid-fast or partly-acid-fast bacterial forms from tubercle bacilli is to grow the tubercle bacilli on glycerin broth in air-tight flasks for two or three months at 37 C., and at the end of that time to remove the seals, substitute sterile cotton plugs, and put the flasks at 22 C. or thereabouts. If the scum is so dense as to shut off the air from the supporting medium, it is desirable to break up the bacillary crusts by gentle shaking of the flask on a few successive days.

Maher has been working with six different strains of human tubercle bacilli—three from pulmonary tuberculosis, one from bone tuberculosis, one from scrotal tuberculosis, and one from glandular tuberculosis. From all of these strains he has been able repeatedly to secure the coccal and bacillary non-acid-fast, gram-negative forms, that did not curdle milk, that usually crackled in the flame, and were identical in every way with the forms found in pure tuberculous sputum, and in the pus from tuberculous lymph-nodes. From none of these six strains of human tubercle bacilli has he been able to grow any of the five large rosaries of streptococci that are so abundant in certain cases of apparently pure tuberculous sputum. But in the first cultures of coccal and bacillary derivatives of tubercle bacilli the water of condensation in the glycerin-agar tubes invariably contains some of the new organisms in chains. And when the coccal derivatives are grown in glycerin-broth or sugar-broth the tendency to grow in chains is very marked. In cultivating in liquid media the older, partly decapsulated bacillary derivatives, it is difficult to keep these granular rods from elongating into streptococcal filaments.

From tuberculous pus, which on microscopic examination showed only long granular tubercle bacilli, Maher claims to have repeatedly grown pure cultures of a beautiful streptococcus, which at first contained in every chain one or more acid-fast granules, evidently akin to the granules in the tubercle bacilli of the pus. On sub-cultures these chains were entirely non-acid-fast. When injected into tuberculous guinea-pigs, these streptococci caused marked focal reactions, and in two series of experiments seemed to have some beneficial influence over guinea-pig tuberculosis.

21. **Action of Acetic Acid on Syphilitic Blood-Strains.**—The purpose of the test described by Sorgatz and Bolend is to demonstrate what they believe to be a relative increase of resistance of the red blood-cells of luetic individuals to hemolytic agents as compared with normal cells. For this purpose they use drops of suspected blood received on filter paper, controlled by normal specimens obtained at the same time and treated in an identical manner.

The reagents used are pure methyl alcohol for fixing the specimens and glacial acetic acid for demonstrating the hemolysis. The latter must be pure, freshly solidified by cold and diluted with freshly distilled water, the dilutions being six in number, namely, 1/5,000, 1/7,500, 1/10,000, 1/12,500, 1/15,000 and 1/20,000, respectively. The blood is obtained preferably from the finger, as the flow can be more readily controlled. It is received on filter paper in drops not more than 3 mm. in diameter. The droplets are cut from the filter paper in such a manner as to show the drop in the center of a small square or oblong of the paper. This must be small enough to enter the test-tube readily. Six such specimens are obtained from each paper and dropped into the test-tubes by means of the forceps. The fingers must not touch the squares and the test-tubes must be clean and dry. The suspected specimens are placed in tubes 1, 3, 5, 7, 9 and 11 and the normal in 2, 4, 6, 8, 10 and 12. The dilutions are now placed in the tubes by means of the pipet, beginning with the highest dilution, 1/20,000, which is placed in tubes 11 and 12, a sufficient amount being used to immerse the papers and an equal number of drops in each tube. The 1/15,000 dilution in then placed in tubes 9 and 10, 1/12,500 in tubes 7 and 8 and so on, the original number of drops being adhered to and the pipet washed in distilled water and thoroughly shaken out before the next is used. The tubes are then slightly agitated to dispose of air bubbles and the rack is placed in a good light to observe the reaction.

The drops of normal blood will begin to disappear almost at once in the stronger dilutions, while the suspected specimens, if positive, will retain their color in a degree corresponding to the activity of the luetic condition. Strongly positive specimens will not be acted on by even the 1/5,000 dilution, while weakly positive ones will resist the 1/15,000 and perhaps the 1/12,500 dilutions, and so on through the various gradations. The reaction should be kept under constant observation for twenty to thirty minutes and the rack should not be agitated as the discoloration of the solutions by the hemoglobin is likely to cloud the appearance of the papers.

The authors state that the test should not be depended on in the absence of ample clinical evidence of syphilis or a careful Noguchi or Wassermann test.

81. Shock: Its Nature and Management.—By correctly estimating the powers of the patient, avoiding all officious meddling, doing well but quickly what must be done, having, as Sir James Paget expressed it, "the courage to do little," when to do more would be harmful, having always in mind the first object of the humane operator, the saving of life rather than the performance of a successful operation, only thus, says Parham, may we hope to avoid witnessing on the operating table the sad spectacle of shock. Parham discusses this interesting subject in great detail, citing freely from the literature.

85. Doctrine of Cleanliness and Public Health.—Experience forces Stiles to the conclusion that there is not an inconsiderable number of physicians in practice who have exceedingly elementary ideas on the subject of cleanliness. He says that an entire book could be written on the condition of the privy one finds at the home of the average physician in small towns and in rural districts. In by far the majority of instances Stiles has seen, these guardians of the life of human beings have the common surface privy, open in the back, scattering soil pollution, breeding flies, and thus providing human excreta as condiment to the food consumed by themselves, their families and their neighbors. The moral to the tale is, he continues, that resolutions adopted by these gentlemen as to the necessity for any given plan of public health legislation are somewhat lacking in weight of professional authority. Some of them seem to think that the only way to bring about a public health reform—much needed as it is—in this country is to put a physician in the president's cabinet. Without taking any stand as to the advisability of the existence of such a cabinet official, Stiles suggests that a full time county health officer who will, among other things, compel these gentlemen to clean up their offices, operating rooms, and privies, and force them to stop spitting on the floor, might contribute somewhat to a reduction of the death-rate. Stiles cites some forceful personal observations.

87. Intravenous Injections of Strophanthin.—The initial injection of strophanthin advocated by Truelsen is a tentative one, and should not exceed 0.5 mg. A lower initial dose must be employed if the injection follows digitalis medication. Also three or four days must be allowed to elapse before giving this injection under these circumstances. If it can be ascertained that pulse, respiration and diuresis are favorably influenced, even though it be slightly and for a short time only, then one is justified in expecting from subsequent larger injections a repetition and augmentation and a continuance of its specific action. In some cases the initial injection will fail to show measurable improvement on pulse, respiration and diuresis, but the subjective improvement, as relief from dyspnea or oppression, or a natural refreshing sleep, etc., will warrant repeated and increased injections. In order to prevent cumulative effects, injections must not be repeated within twenty-four hours. A safe rule regarding repetitions is not to make another injection until the benefits obtained from the previous one are no longer maintained. During the earlier period of the course three to four injections a week; later perhaps only one will be found necessary. The average dose is 1 mg. and should only be exceeded in full realization that *one* is using a powerful drug.

93. Mobilization of Ankylosed Joints.—In all the experiments made by Allison and Brooks, the process of healing of the joint surfaces from which the cartilage was removed was the same. Following the injury the ends of the epiphyses acted in a manner strikingly different from that seen after injury to the diaphyses. There was very little new bone formation from the denuded bone area at the end of sixty days. The new bone formation seen was always under the joint cartilage which had not been removed. The denuded joint surfaces were at the end of five days covered with granulation tissue which grew from the marrow spaces. This granulation tissue developed into fibrous tissue. With two denuded joint surfaces approximated directly the granulation tissue united the two surfaces. This process obviously leads to a fibrous ankylosis, which, according to Hoffa, is the primary stage of osseous union.

With the interposition of fascia lata, either in free pieces or in pedunculated flaps, the direct union of the denuded joint surfaces was prevented only in case the fascia transplant underwent necrosis and absorption. In those instances in which the transplanted fascia persisted in parts, the persistent islands acted as adhesions between the joint surfaces. In the experiments with fascia there was no evidence of any advantage of a pedunculated transplant. On the contrary, in each instance the pedicle persisted as an intra-articular band which checked joint movement. With the fascia fixed and impregnated with silver, the union of the denuded joint surfaces was prevented. The more irritating chromicized pig's bladder membrane always led to a much greater amount of fibrous tissue formation, and the fibrous tissue formed in every instance more or less completely united the opposed joint surfaces.

The relatively small amount of new bone formation from the ends of the bones in the joint, the authors believe, makes the prevention of union between raw joint surfaces a problem which is identical with that of cavity production in soft parts. With the transplantation of living tissue into soft parts, in case the transplant preserves its vitality, it heals in the tissues without cavity formation. If the insert undergoes necrosis and absorption, or is an absorbable, non-living substance which excites very little inflammatory reaction, it disappears, leaving a cavity. If the insert is of such a nature as to set up a marked inflammatory reaction, the tendency of the process is to close the cavity occupied by the insert in a manner similar to the closing of an abscess cavity.

94. **Attempts to Mobilize Stiffened Joints.**—In the majority of cases the results of the attempts at the mobilization of stiffened joints which have been made by Osgood have been far from satisfactory. He is inclined to believe, in the light of his experiences, which he believes may be duplicated in the hands of other surgeons, that unilateral, painless, bony ankylosis of the knee, hip, shoulder, and possibly elbow, should be submitted to arthroplastic operations at the present stage of our technic only after a free discussion with the patient and a realization on his part of the prolonged and often painful after-treatment, and the somewhat uncertain nature of the results. He urges as far as possible the concentration of these cases in the hands of a few men, preferably only one in a city, who will fit himself by study to be at least conversant with the most successful methods.

Osgood reports results of 18 arthroplastic operations, 6 on the hip with good results in 1, 7 on the knee with good results in 3, 4 on the elbow with good results in 1 and 1 on the jaw, which was successful. He used to prevent ankylosis recurring, either chromicized pig's bladder as recommended by Baer or pieces of free fascia removed from the fascia lata at the time of operation. In two of the hip cases he turned in pedunculated flaps of tissue. In only one case has any considerable inflammatory reaction followed the use of the pig's bladder membrane, but in every case there has been a slight discharging sinus, sometimes coming on as late as three weeks after the operation and often persisting for months. In three cases the membrane itself, in whole or in part, has been extruded several weeks after the operation; but that has not seemed to interfere with persisting mobility. In the cases in which free fascia flaps have been used, the healing has been by first intention, and no sinuses have occurred except in the one case of a tuberculosis developing in the operated elbow six months after the arthroplastic operation. Although generous portions of fascia lata have been excised (4 inches square) there has been no subsequent muscle hernia or any evident weakness.

Osgood concludes his paper as follows:

> I confess the end results of some of the cases have given me pause. When we obtain a joint with useful motion persisting for six months and then gradually see this motion disappear, in spite of careful after-treatment, owing to joint sensitiveness and to soft part contractures, and when we may watch the overgrowth of bone about our seat of operation continue for long periods, we owe it to our patients to explain these possible contingencies until we know how to surely prevent them. Payr has wisely said that we must carefully select our cases both in relation to occupation, social status *and temperament, before we attempt by the methods now* advocated to mobilize stiffened joints, and the writer would add that in addition to this selection our prognoses should be most guarded as to painless or useful motion and as to function.

96. **Drainage of Upper Intestinal Loop for Ileus.**—The toxic element, McKenna believes, fully explains the cause of death in acute bowel obstruction. He is of the opinion that when the physiologic balance of the normal intra-enteric secretion (the secretion from the duodenal mucosa, probably from Bruner's glands) is disturbed, the secretion becomes profoundly toxic, and unless this physiologic balance is quickly restored, a fatal termination surely and swiftly ensues. In other words, any influence that leads to an upper intestinal paresis sufficient to stop peristalsis, blocks the normal flow of the duodenal secretion as effectively from the point of view of ileus, as if the gut were mechanically closed. He is of the opinion that the duodenal stasis produced by paresis of this portion of the gut may be compared to the duodenual stasis produced in the dog by closing the lower end of the duodenum.

The blocking up of the duodenal secretion may become a fatal factor in one of two ways: First, by direct absorption into the blood of a powerfully toxic substance; second, because of the improper mixture between the secretion of the duodenum and the secretion from the lower intestinal tract. McKenna has up to the present successfully operated eight cases of acute bowel obstruction, by enterostomy. In the early cases it was more chance than any other factor that led him to make an enterostomy high in the small intestine. At any rate, the opening was made high enough so that by means of long catheters introduced into the bowel, pancreatic secretion was poured out on the abdominal wall.

The presence of pancreatic secretion was first detected because of the very marked excoriation produced on the skin. In these cases, and in subsequent cases, McKenna noted a relationship between the welfare of patients and the presence of pancreatic secretion at the intestinal opening. The presence of pancreatic secretion at the site of the enterostomy proved the presence of duodenal secretion. The operation of enterostomy which is always performed under local anesthesia, is made well above and to the left of the umbilicus as this location gives entrance to the abdominal cavity at a point where the upper portion of the jejunum can be picked up most accurately.

McKenna always picks up the first loop of small intestine that presents itself at the site of the opening, which he believes in a large percentage of cases will give a loop of small intestine well up in the jejunum. Whether this operation be performed by the suture method or by a mechanical device, two principles must obtain to insure success—accurate and immediate approximation of the serous covering of the bowel to the cut edge of the skin and drainage of the upper loop of intestines, at least, by means of a tube. McKenna has also *adopted a definite plan in closing the intestinal* fistula. A resection of the fistula with a lateral anastomosis of the intestines is made.

97. **Bone and Periosteal Transplantation.**—The authors were unable in any experiment to reproduce bone from free periosteal transplants into the subcutaneous tissue and muscle. They were unable to reproduce bone in the periosteal flap raised, left in contact with the bone, passed through muscle and again contacted with periosteum, with one single exception where there was a small nodule of bone formed apparently in the free end of the flap, corresponding to another nodule formed on the shaft of the bone opposite, leading them to believe that the bone in the tip of the free periosteal flap was osteoblasts raised from the corresponding area on the shaft of the bone and also because no bone had formed

anywhere else in the flap. They were unable to reproduce bone in any experiment from free bone transplants, without periosteum, into the subcutaneous tissue and muscle, regardless of the age of the transplant. Absorption was the rule in every case. They were unable to reproduce bone in a single experiment where bone was transplanted free, periosteum left intact, into the muscle or subcutaneous tissue. These transplants were uniformly absorbed. They were uniformly able to reproduce bone when transplanted and contacted with living bone, if it were in position where it had a function to perform. Other necessary conditions being present for its reproduction, bone reproduces bone without the aid of periosteum. The transplants that were contacted with living bone and had no function to perform were inclined to absorption. While periosteum may be an aid to the life and growth of bone, the authors were not able to prove in any experiment that it was at all essential.

98. **Mortality of Suprapubic Prostatectomy.**—Cabot urges strongly the importance of paying attention to the three important factors at present influencing the mortality of suprapubic prostatectomy: the anesthetic, the production of shock by traumatic operating, and the inefficient control of bleeding. When these factors are reduced to a minimum as sources of danger, suprapubic prostatectomy will be the method of election for all cases of adenomatous enlargement of the prostate, and the perineal operation will have passed quietly into history.

101. **Ovarian Pregnancy Located in Graafian Follicle.**—The specimen examined by Mall and Cullen showed conclusively that the ovum had lodged itself in the Graafian follicle, undoubtedly in the one from which it came, indicating that the sperm must have entered the follicle after it had ruptured. The fertilized ovum then found lodgment in the follicle, around which the corpus luteum developed. As in other cases which have been reported, no decidua was formed showing that the decidua is not of embryonic origin.

102. **Malignant Disease of Retained Testicle.**—The records of fifty-nine cases, one of them his own, were examined by Bulkley. He found that malignant disease of the abdominal testis is relatively rare, but frequently overlooked. In general hospital male admissions it is seen about once in each 60,000 cases. About one in every four cases of malignant abnormally situated testicle is found within the abdomen. About one malignant abdominal testicle occurs to each fifteen malignant scrotal testicles. About one of each seventy-five abdominally retained testes will become malignant. Cases occur mainly during the years of greatest sexual activity, may occur in apparent females, and are slightly more frequent on the right than on the left side. The structure of the tumors differs markedly, but most of them are probably teratomas. Other associated congenital malformations are fairly frequently found. Symptoms do not occur until the size of the tumor or its metastases cause pressure. The prognosis is bad. Of the fifty-nine reported cases, only three are known to be alive and well after two years. Treatment should be excision, preferably before the onset of symptoms and after the age of puberty.

106. **Treatment of Acute Gonorrheal Epididymitis.**—Cunningham believes that epididymotomy offers the best means of ending an acute gonorrheal epididymitis and allaying the symptoms dependent on this pathologic condition.

109. **Treatment of Abdominal Adhesions.**—In the case cited by Reichelderfer before final closure of the wound, the abdomen was filled with salt solution. As soon as the patient reacted from the anesthetic she was placed in a sitting position and kept there. On the third day she was allowed to get out of bed and stand on her feet as much as her strength permitted. Within a few days she was walking around the ward, but still rested and slept in a partially upright position. She left the hospital in four weeks; she suffered no pain and improved rapidly, gaining thirty pounds in the next six months. She resumed her work and has continued well to the present time, a period of nearly four years. From his experience with this case and from reports of many similar cases repeatedly operated on, Reichelderfer thinks we must admit the impossibility of permanently removing these adhesions; but he believes many of these desperate cases can be greatly benefited by this postural treatment after the adesions are broken up at operation.

For this plan to be effective it is necessary, first, that all or nearly all adhesions be broken up, especially on the sensitive parietal peritoneum so that the abdominal contents may adjust themselves at as low a level as possible immediately after the operation; second, that the raw surfaces must be kept apart for twelve or eighteen hours by salt solution, until the patient can be placed in the upright position, which must be done as soon as possible as it is known that raw peritoneal surfaces adhere very quickly.

111. **Modification of Rectus Fascial Flap in Inguinal Hernioplasty.**—The method suggested by Rhodes appears to him to result in a restoration to a condition very closely approximating that obtained by the Bassini operation. He has employed it in only one case, an old, indirect hernia, with very gratifying result. Approach to the operative field is made by a Ferguson incision with the convexity directed toward the midline of the abdomen, to allow easy access to the rectus sheath. The cord, sac and contents are treated as in the Bassini operation. After the sac has been tied off and returned to the abdomen the cord is crowded into the upper angle of the inguinal canal as far as possible, forcing it closely against the fibers of the internal oblique and transversalis at their origin from Poupart's ligament. With the spine of the pubis as a center, a distance is marked off on the rectus sheath equal to the distance from the spine to the cord at its entrance to the abdomen. This gives the level for the transverse section of the rectus sheath.

The entire thickness of the rectus sheath is now converted into a triangular flap by an upper transverse incision across the width of the muscle of the corresponding side, and a longitudinal incision near the midline of the abdomen, meeting the first incision above and prolonged down as far as the symphysis if necessary. The external oblique is now split in the direction of the fibers and the flap is pulled through the slit thus formed. The flap is sutured to the posterior shelving edge of Poupart's ligament, taking the place of the conjoined tendon, and the cord transplanted. Operation concluded as in a typical Bassini operation.

1. **Parasyphilis of Nervous System.**—Parasyphilis of the nervous system is looked on by the authors as being a purely clinical conception. It is a diseased state which may affect any part of the brain or spinal cord; the manifestations of tabes dorsalis and dementia paralytica can only be erected into two clinical divisions by an arbitrary selection of signs and symptoms. Some forms of progressive muscular atrophy, lateral and combined sclerosis, primary optic atrophy and periodic epileptiform attacks may be equally definite mani-

festations of parasyphilis. Parasyphilis is slightly, if at all, amenable to antisyphilitic treatment with compounds of arsenic and mercury, probably because these bodies do not enter the essential structures of the central nervous system. Parasyphilitic states are peculiarly liable to arise after mild syphilitic infection.

Sixty per cent. of cases of tabes dorsalis have suffered from at most a primary sore, and in many instances the whole course of the initial infection was run under cover of a gonorrhea. In dementia paralytica and in active, untreated cases of tabes dorsalis and taboparesis, the cerebrospinal fluid yields a positive Wassermann reaction, often of great strength. With acute or chronic syphilis of the nervous system, other than parasyphilis, the behavior of the cerebrospinal fluid depends on the extent to which the spinal cord and its membranes, including those of the brain-stem, are affected. Thus, most cases of meningomyelitis show a strong positive reaction in the cerebrospinal fluid, while cerebral lesions tend to give a weakly positive or even a negative reaction. Antisyphilitic treatment has a profound effect on the positive reaction in syphilitic meningomyelitis, and the cerebrospinal fluid may give a negative reaction after a few months. But in cases of parasyphilis no obvious change occurs in consequence of such treatment, within any comparable period.

The authors believe further that all tertiary and "parasyphilitic" manifestations are expressions of the reaction of hypersensitized tissues ("hyperallergic"). That is to say, during the previous stages of infection the tissues have been so altered that they react more violently to a smaller dose of the spirochetes or its toxins. Gummatosis is the reaction of hypersensitized connective tissues and blood-vessels, while "parasyphilis" is a hyperallergic reaction of the essential nerve-elements and neuroglia. The consequences of this hyperallergic reaction in the tissues of the central nervous system is death of any set of fibers or cells which happens to be attacked, and proliferative reaction on the part of the neuroglia within the same territory. Thus, the clinical manifestations of "parasyphilis" are an expression of the reaction and necrosis of hypersensitized areas of the nervous system, evoked by reappearance of the *Spirochaeta pallida*. This hypersensitive ("hyperallergic") state of the tissues of the central nervous system is produced, in all probability, by the passage of the spirochetes or their toxins up the nerves from the skin and mucous membranes during the secondary period. But it is also conceivable that it may be due to a slight "encephalitis" during this stage of infection.

The headache and lassitude, unaccompanied by any gross nervous lesions, which so frequently occur during the secondary stage, possibly represent clinically the period during which sensitization occurs. Thus, parasyphilis is a clinical conception which comprises the manifestations of a series of diseased states. From the pathologic point of view the term is inadmissible. These states depend on the reaction of hypersensitized tissues to the spirochete or its toxins, and this reaction is as truly syphilitic as the production of gummata. The difference between the consequences of the tertiary and of the "parasyphilitic" process lies in the nature of the tissues participating in the reaction. In the one case the connective tissue is capable of repair and the focus is readily reached by the remedial agents. In the case of "parasyphilis" reaction of the essential nerve-elements leads to their death and antisyphilitic remedies cannot readily reach the spirochetes.

7 Case of Corneal Ulceration Associated with Presence of Spirilla and Fusiform Bacilli. W. G. Goudie and J. R. Sutherland.

4. Diagnosis of Pulmonary Tuberculosis.—Careful and accurate percussion, Lees says, is of primary importance in the diagnosis of early pulmonary tuberculosis, both in the child and in the adult, and that it is capable of detecting the disease at a much earlier period than is possible by any other method of investigation. It is a method which does not require any expensive or complicated apparatus, which is independent of the laboratory and its products and which calls only for care and accuracy on the part of the doctor. When the general practitioner of medicine realizes what is possible for him in diagnosis by careful percussion and auscultation, and determines his treatment in accordance with the knowledge which he may thus easily acquire, the final extinction of the disease known as pulmonary phthisis will have become a possibility.

9. Typhoid-Paratyphoid Vaccination with Mixed Vaccines.—The mixed vaccine Castellani uses at the present time contains per cubic centimeter 500 million typhoid, 250 million paratyphoid *B*, and 250 million paratyphoid *A*, and is prepared either from broth cultures or emulsions in physiologic salt solution. A little compound solution of cresol (0.2 per cent.) is added. He gives 0.6 c.c. the first time, and doubles the dose a week later, and, whenever possible, a third dose two weeks from the first. In some cases, however, he gives only ½ c.c. the first time, and 1 c.c. the second. Very thin, delicate individuals and young women receive a little less. Children between 8 and 15 get a quarter to half the adult dose. The inoculation of the mixed vaccine is followed by a local and general reaction which, as a rule, is not distinctly severer than after the inoculation of simple typhoid vaccine. Three or four hours after inoculation the region on the arm where the injection has been made becomes painful and red, and fever may supervene, which does not last longer, as a rule, than twenty-four hours to thirty-six hours, and does not in most cases incapacitate one for work.

As Castellani does not believe that the immunization given by bacterial inoculation lasts in man very long, he generally advises people to be vaccinated once every two years, or even once a year.

17 *Petrol (Gasoline) as Therapeutic Agent. G. A. Stephens.

17. Petrol as Therapeutic Agent.—Stephens recommends petrol or gasoline as a scalp cleanser, especially when the dandruff is excessive; in alopecia areata; in cases of pediculi capitis; for wounds of the scalp, enabling the surgeon to remove all surgical "dirt" in an easy and thorough manner, and often times without having to shave the scalp; in pustular eruptions of the beard, especially in cases in which the "rash" can be traced to such a cause as discharge from the external meatus. Applied early in cases of barber's rash or in scabies, in cases of cracked nipples, for soft corns, burns of all kinds, and especially those produced by the spluttering of hot metal at steel, copper or spelter works, are greatly benefited by the early application of petrol.

The value of petrol in burns is, in Stephens' opinion, due to the fact that it destroys all germs that have been conveyed from the filthy clothes on to the wound, and at the same time interferes with the broken-down, half-burnt skin-cells, from which enzymes have been set free. In operations he has found petrol extremely useful and effective, and possessing none of the irritating and disappointing qualities of tincture of iodin. Before the incision the part should be well scrubbed with cotton wool soaked in petrol, and the instruments, if they be suspected, can be thoroughly disinfected by putting them in petrol for a few minutes: after the stitches are inserted all that remains to be done is to swab with petrol and dress with an orthodox dry dressing. One word of warning is sounded as regards the use of petrol, and that is that it should never be handled near a fire or a naked light, such as gas, or a candle, or an oil lamp, for on account of its great volatility it readily gets ignited, and with disastrous consequences.

24. **Inheritance of Mental Characters.**—From our knowledge and experience Hyslop believes it to be warrantable to make the following assumptions: There are certain fundamental capacities of mind which cannot be demonstrated as being the result of ancestral experience, nor do they necessarily represent acquisitions made in the life history of the race. These capabilities need not necessarily manifest themselves at the early periods of life, nor are they entirely dependent on the environment, which acts on the mind through the nerve structures. The conditionings of such mental developments do not invariably follow what we imagine to be the proper laws of organic and nervous development. Genius, although invariably associated with, or symptomatic of, a neuropathic process, is, nevertheless, often closely allied to the neuropathic diathesis, as evidenced in the histories of past and present geniuses. So far from being the result of progressive achievements of the intellect are some forms of genius that they may more truly be classed with the degenerate than with the healthy.

35. **Gunshot Injuries of Arteries.**—Makins discusses this subject from the viewpoint of the military surgeon. He takes up, in order, the changes in the form of the bullet; injuries to blood-vessels by modern and older bullets; contusion of the vessel wall; comparative frequency and results of various forms of wounds; anatomic characters of the wounds; primary hemorrhage; spontaneous cure as an immediate process; remote process of healing; aneurysmal varix; secondary hemorrhage; the development of aneurysms; the treatment of wounded arteries; treatment of arterial hematomas and aneurysms; direct and proximal ligature; modified operation of Antyllus—extirpation; the method of suture; the immediate vitality of the limb; the later nutrition of the limb; thrombosis; other accidents.

Under this head he refers to the comparative results obtained in 41 cases of ligature and 24 cases of suture in the Belgrade State Hospital, as follows: ligature, 41 cases; gangrene, 6 cases (14.6 per cent.), and deaths, 4 cases (9.75 per cent.). One death due to softening of the brain and pneumonia after ligature of the carotid, 1 from secondary hemorrhage, 1 from sepsis and 1 from anemia and exhaustion. Suture, 24 cases; gangrene, 3 cases (12.5 per cent.), and deaths, 2 cases (8.3 per cent.).

The operation of choice for primary hemorrhage from a gunshot wound in the field is direct ligature. Primary ligature should be confined to cases in which hemorrhage is obviously endangering life. As to intermediate operations the wounds are ill-suited to any form of treatment except the simplest. Secondary operations may be undertaken at an average period of about four weeks and practically resolve themselves into operations for aneurysms of three varieties.

A consideration of the wounds of arteries by bullets of small caliber and their treatment, Makins states, shows that progress in this branch of military surgery has taken the direction of increased conservatism and expectancy. In this it is no exception to that observed in every other chapter of the subject. Non-interference in fractures has become almost a general rule, operations on joints have decreased in number almost to a vanishing point, injuries to the nerves are seldom the subjects of primary operative treatment, and we have seen that those of the vessels come into the same category. Still more striking is the expectant attitude maintained by the surgeon in the case of wounds traversing the great body cavities, in all of which primary operations have become progressively fewer.

36. **Sydenham's Chorea.**—Langmead does not recognize a specific remedy in the treatment of chorea. In some cases after a short rest in bed the symptoms rapidly and unexpectedly subside; in others, apparently similar, the chorea persists in spite of the use of several therapeutic agents. There is a logical basis for the administration of sodium salicylate or acetosalicylic acid because of their effect on rheumatism—and Langmead says, most of us regard chorea as a rheumatic manifestation; but, again in following a long series of patients treated in this way it is difficult to be sure that these drugs are capable either of diminishing the severity of an attack or of shortening its duration. Langmead usually prescribes one of these drugs. They are especially indicated if the temperature is raised, and should be pushed in sufficient doses to bring it down to normal. He has not found that these large doses have a better effect than others of more moderate size. If salicylates are used, whether in large or small doses, certain precautions should be taken to avoid poisoning symptoms. Those which are most to be feared are due to acid-intoxication, and resemble somewhat diabetic coma. The child becomes drowsy, her respirations deep and noisy (air hunger), vomiting occurs, the breath is sweet from the presence of acetone, and acetone and diacetic acid are found in the urine. If the salicylate is not discontinued the child may sink into coma and die, though this is a very rare occurrence.

These symptoms may be avoided if two precautions are exercised—first, the bowels should always be kept well open; and, second, twice as much sodium bicarbonate should be given as sodium salicylate. Before beginning salicylate treatment it is well to administer a purgative, and the bowels should have been opened within the twelve hours preceding any increase in the dose. By attention to these details all anxiety concerning acid-intoxication disappears. Langmead has not been impressed by the value of arsenic, while it has been his experience to encounter more than one case in which arsenical neuritis was produced—a condition which takes far longer to get well than that for which the drug was given.

festations of parasyphilis. Parasyphilis is slightly, if at all, amenable to antisyphilitic treatment with compounds of arsenic and mercury, probably because these bodies do not enter the essential structures of the central nervous system. Parasyphilitic states are peculiarly liable to arise after mild syphilitic infection.

Sixty per cent. of cases of tabes dorsalis have suffered from at most a primary sore, and in many instances the whole course of the initial infection was run under cover of a gonorrhea. In dementia paralytica and in active, untreated cases of tabes dorsalis and taboparesis, the cerebrospinal fluid yields a positive Wassermann reaction, often of great strength. With acute or chronic syphilis of the nervous system, other than parasyphilis, the behavior of the cerebrospinal fluid depends on the extent to which the spinal cord and its membranes, including those of the brain-stem, are affected. Thus, most cases of meningomyelitis show a strong positive reaction in the cerebrospinal fluid, while cerebral lesions tend to give a weakly positive or even a negative reaction. Antisyphilitic treatment has a profound effect on the positive reaction in syphilitic meningomyelitis, and the cerebrospinal fluid may give a negative reaction after a few months. But in cases of parasyphilis no obvious change occurs in consequence of such treatment, within any comparable period.

The authors believe further that all tertiary and "parasyphilitic" manifestations are expressions of the reaction of hypersensitized tissues ("hyperallergic"). That is to say, during the previous stages of infection the tissues have been so altered that they react more violently to a smaller dose of the spirochetes or its toxins. Gummatosis is the reaction of hypersensitized connective tissues and blood-vessels, while "parasyphilis" is a hyperallergic reaction of the essential nerve-elements and neuroglia. The consequences of this hyperallergic reaction in the tissues of the central nervous system is death of any set of fibers or cells which happens to be attacked, and proliferative reaction on the part of the neuroglia within the same territory. Thus, the clinical manifestations of "parasyphilis" are an expression of the reaction and necrosis of hypersensitized areas of the nervous system, evoked by reappearance of the *Spirochaeta pallida*. This hypersensitive ("hyperallergic") state of the tissues of the central nervous system is produced, in all probability, by the passage of the spirochetes or their toxins up the nerves from the skin and mucous membranes during the secondary period. But it is also conceivable that it may be due to a slight "encephalitis" during this stage of infection.

The headache and lassitude, unaccompanied by any gross nervous lesions, which so frequently occur during the secondary stage, possibly represent clinically the period during which sensitization occurs. Thus, parasyphilis is a clinical conception which comprises the manifestations of a series of diseased states. From the pathologic point of view the term is inadmissible. These states depend on the reaction of hypersensitized tissues to the spirochete or its toxins, and this reaction is as truly syphilitic as the production of gummata. The difference between the consequences of the tertiary and of the "parasyphilitic" process lies in the nature of the tissues participating in the reaction. In the one case the connective tissue is capable of repair and the focus is readily reached by the remedial agents. In the case of "parasyphilis" reaction of the essential nerve-elements leads to their death and antisyphilitic remedies cannot readily reach the spirochetes.

4. **Diagnosis of Pulmonary Tuberculosis.**—Careful and accurate percussion, Lees says, is of primary importance in the diagnosis of early pulmonary tuberculosis, both in the child and in the adult, and that it is capable of detecting the disease at a much earlier period than is possible by any other method of investigation. It is a method which does not require any expensive or complicated apparatus, which is independent of the laboratory and its products and which calls only for care and accuracy on the part of the doctor. When the general practitioner of medicine realizes what is possible for him in diagnosis by careful percussion and auscultation, and determines his treatment in accordance with the knowledge which he may thus easily acquire, the final extinction of the disease known as pulmonary phthisis will have become a possibility.

40. Vaccines Graduated by Their Opacity.—Bruce's method is to grow the cultures on agar, blood agar, etc., and to make an emulsion of the growth with normal saline. The emulsion is then placed in a ⅝ inch test-tube and diluted with normal saline until it is possible to read clearly certain type through the medium of the tube containing the emulsion. The vaccine is then sterilized by heat or it is sterilized by chloroform or by ether. Satisfactory results were obtained by all three methods of sterilization. If the vaccine is to be used by himself, Bruce uses it in the above density, making the initial dose in every case 0.1 c.c. If the vaccine is to be used by a general practitioner, Bruce dilutes the original emulsion to 2½ or 5 volumes, and the dose will then be either 0.25 or 0.5 c.c. Subsequent doses can be increased or diminished according to the reaction obtained from the first injection.

Bruce appends a list of the results in eighty-eight patients treated by vaccine graduated in the manner described.

44 *Gastric Crises of Tabes and Their Operative Treatment. J. Tinel.
45 Dilatation of the Pylorus from the Mouth. M. Einhorn (New York).
46 Surgery of Pelvic Colon. M. Patel.

44. Gastric Crises of Tabes and Their Operative Treatment.—Tinel discusses the anatomic bases for gastric crises and explains why those for which the splanchnic nerves are responsible are the only ones amenable to the operative measures proposed to date. His illustrations showing the inflammatory processes in the dorsal roots confirm this, as also the existence of foci of meningeal irritation along the course of the origin of the splanchnic nerves. The pneumogastric crises differ from the splanchnic. The vomiting factor in the crisis may be of pneumogastric origin, but this is only a minor element in the gastric crisis of pain. Both pneumogastric and splanchnic nerves may be involved, but if the splanchnic pains can be abolished the other elements in the attack are comparatively negligible. He discusses the various operative measures in vogue, stating that Foerster's operation has a record of 31 per cent. mortality in the sixty cases in which it has been done; twenty-seven of the patients were cured partially or completely and six much improved. The failures in eight cases were probably due to the fact that not enough roots were severed.

Tinel regards this operation as logical and effectual, but too serious for any but desperate cases. He says of Franke's method of tearing out the intercostal nerves, hoping thus to tear away with them the rami communicantes, the origin of the splanchnic nerves, that its chief danger lies in tearing the meningeal sheath too, while if it does not pull out the ganglion with the nerve root it fails of its purpose. The record to date, he says, is eight cures, nine recurrences, one improvement and two deaths. At the same time, he says, at present it is the easiest and simplest operation. Ligating the dorsal spinal roots between the ganglion and the dural sac must effectually block the reflex arc and eventually entail complete degeneration of the sensory dorsal fibers. This simple and rapid operation thus amounts virtually to a laminectomy. The only drawback is that the anterior motor root must be included in the ligature. Franke's operation, however, has demonstrated that this can be done with impunity. Slight paresis of the epigastric musculature may result, as Leriche and Cotte have already observed, but this is easily counteracted by wearing a belt.

Archives de Médecine des Enfants, Paris

December, XVI, No. 12, pp. 881-984

47 *Choreiform Manifestations in Epidemic Poliomyelitis. (Paralysie infantile choréique.) A. Netter and L. Ribadeau-Dumas.
48 *Salvarsan in Treatment of Syphilis in Children. A. Galliot.
49 Mode of Infection with Tuberculosis in Young Children. (Voies d'accès de la tuberculose chez les enfants.) O. Medin.
50 Hypophysis Tumor Syndrome in Young Man. (Diabète insipide, dystrophies générales avec prédominance aux organes génitaux; ensemble symptomatique lié à une insuffisance hypophysaire.) A. Mamrot.

47. Choreic Poliomyelitis.—The two typical cases reported show that epidemic poliomyelitis may occasion choreiform movements, this jerking keeping up for days or weeks. It generally precedes by a few hours the development of the paralysis, and is generally transient. This choreic type is more common in monkeys inoculated with the virus than in man. The choreiform phenomena may exist alone, and the cases that have been published of alleged "paralytic chorea" were probably instances of this.

48. Syphilis in Children.—Galliot cites statistics which show that 82.9 per cent. of the children died before or soon after birth when the mothers—217 in all—had florid syphilis and were given energetic mercurial treatment. In 291 other pregnant women whose syphilis was in a latent stage during the pregnancy and who took systematic mercurial treatment, 75.9 per cent. of the children were viable at birth; 91.72 per cent. were viable of the children of 145 women given salvarsan during pregnancy. Galliot ranks salvarsan above all other measures in treatment of syphilis in pregnant women. Given systematically, he says, it permits the hope of healthy offspring free from inherited taint, while its use seems free from danger for mother and child. But after the child is born, he continues, salvarsan gives slight if any benefit, while it is liable to prove directly harmful for the infant. Mercury is far superior to salvarsan in treatment of infants. Salvarsan comes into its own again, however, for older children. It seems to act rapidly and unfailingly on already developing lesions. It also seems to act effectually on syphilitic dystrophies, especially when combined with mercury.

The Wassermann test is not of much use in diagnosis of syphilis in children. The courses of treatment for children should be as long as for adults. He cites a number of authors who have reported excellent results from salvarsan in treatment of children with inherited syphilis, and adds five cases from his own experience. One of his patients was a girl of 10 with inherited taint manifested in a process in the right knee with ankylosis, slight albuminuria and keratitis with no apparent benefit from twenty-five injections of mercury. She was then given in the course of about two years 0.75 gm. of salvarsan by intravenous injection, 1 gm. intramuscular and 1.4 gm. of neosalvarsan intramuscular. By the fourth injection the knee trouble began to improve, and finally the ankylosis retrogressed and the knee is now used normally; the eyes have been in good condition for over six months. In the second case the boy of 10 took a course of neosalvarsan to a total of 1.1 gm. When 0.6 gm. had been reached the ankylosis had entirely subsided but the Wassermann was still positive. By the end of the course all signs and symptoms had subsided.

54 *Serotherapy by Proctoclysis. (Le "sérum continu intrarectal" en médecine infantile.) E. Lesné.

54. Saline Infusion by Proctoclysis for Children.—Lesné has applied to infants what he calls *la méthode de Murphy* in the place of subcutaneous injection of artificial serum. The tolerance was perfect even in the youngest and there is no contraindication to the method, for not even diarrhea is influenced by this drop method. He administered thus 50 or 100 c.c. of isotonic serum or 4 per cent. solution of sugar and found that it was absorbed as rapidly as by subcutaneous injection. He reports excellent results from it in children of all ages with gastro-enteritis, cyclic vomiting, acute alimentary anaphylaxis and typhoid fever. In some cases he added a little hexamethylenamin or epinephrin and states that the action of the latter was more effectual by the rectum than by the mouth.

56 *Turpentine Injections in Children Péhu and Pillon
57 *Obesity in Children Showing the Characteristics of Genital Adiposity G Mouriquand Commenced in No 48

56 **The Turpentine Fixation Abscess in Children**—After reviewing the meager literature on the subject of the application to children of Fochier's method of therapeutic aseptic fixation abscess, Péhu and Pillon give their results in seventy eight cases, including the so called primary bronchopneumonia following various infections, such as whooping cough, diphtheria, scarlet fever and measles, and in tuberculosis They gave an injection of pure turpentine (0 5 c c) in children under two years of age and 1 c c in children above that age The age of the patients varied from a few months to 12 years No harmful effects were observed in even the youngest children The injections were made deep into the cellular tissue of the abdominal wall There was always a local reaction in the form of an abscess The results in the tuberculous cases, which were very far advanced, were not particularly satisfactory, and hardly more so in the secondary bronchopneumonia, but in eighteen cases the fixation abscess was followed by rapid improvement and recovery Thirteen times the injections were without effect and the patients died In three cases the recovery was probably not due to the turpentine, as it did not take place till long after the formation and opening of the abscess

57 **Obesity in Children.**—Mouriquand discusses the pathology, symptomatology and treatment of pathologic obesity in children Associated with the excessive development of fat there is atrophy of the reproductive glands A point of interest is the extreme degree of tolerance for carbohydrates, and the fact that these patients are frequently the children of diabetics They are liable to become diabetic themselves later in life, and the carbohydrate tolerance should be carefully watched The condition is generally agreed to be due primarily to decreased function of the posterior lobe of the hypophysis but other glands are doubtless involved in its causation The condition is amenable to surgical treatment if the affection of the hypophysis is due to tumors or cysts Theoretically it should be cured by extract of hypophysis but in practice the results of this treatment are variable, being best when the fresh extract of the gland is given. Two boys were treated by Weill by compressing the veins of the spermatic cord with a truss pad on each side This auto organotherapy caused a congestive increase in the size of the testicles and this was followed by a decided improvement in the obesity (See Paris Letter in The Journal, Nov 8, 1913, p 1730)

64 Turpentine Tampon in Puerperal Endometritis P Delmas
65 Uncontrollable Vomiting of Pregnancy (Deux cas de vomissements incoercibles traités par l avortement provoqué) L Dubrisay

62 **Dysmenorrhea and Organotherapy.**—Dalché reviews the various causes which may be responsible for painful menstruation, such as defective development of the genital organs, the ovaries in particular, abnormal ovulation, disease or other causes for the pain in the ovaries, in some cases the cause for the pains must be sought in the glands with an internal secretion, especially the thyroid, and local or radiating neuralgias may be the cause for the dysmenorrhea in others There is still another class of cases in which spasmodic contraction is the source of the pains, defective development of the uterus may be responsible for this or it may be started, maintained or aggravated by pain in the ovaries The spasm may be more painful when there is any mechanical hindrance to the distention of the ovaries and uterus during the menstrual congestion Treatment therefore must vary according to the indications in each individual case Stenosis or atrophy of the cervix should be mechanically combated by dilatation or possibly Pozzi's logical operation for the purpose But the pains may persist even after the outlet has been rendered readily permeable In this case and when the organs seem to be sound, a course of thyroid treatment may restore the balance between the internal secretions He has frequently found it effectual in regulating menstruation, increasing the menses to normal proportions and without abnormal pain He gives small doses of pulverized thyroid, 0 025 to 0 05 or even 0 1 gm a day, keeping this up for a month or more to get the full benefit of its stimulating and regulating action on the functioning of the ovaries The patient must be kept under close supervision during the course, suspending the organotherapy if the pulse goes over 100 or at least materially reducing the dosage After the first month he has the thyroid treatment continued only during the ten days preceding the date of menstruation Sometimes he has found it better to alternate ovarian and thyroid treatment, thyroid in the morning and ovarian tissue at evening, or giving the ovarian treatment continuously for three days and then the thyroid continuously for the same length of time and then resuming the ovarian treatment

He has never had any mishaps with this treatment and has been more successful with it than ever before in the management of dysmenorrhea The only disadvantage is that it generally has to be kept up for months or resumed occasionally to obtain durable improvement or a complete cure To relieve the pain during an attack he gives laudanum and antipyrin, 10 to 1, in a rectal enema or with sodium bromid in place of the antipyrin Relief may be obtained from hot douches on the feet front of the legs and inner side of the thighs, with moist heat to the abdomen Sedative liniments and pomades may also prove useful, or even a blister The patients should guard against constipation, lead a quiet life and keep in bed during the menstrual period It is a frequent experience that if by vigorous means it is possible to ward off the pain with menstruation once, twice or three times in succession, the tendency to dysmenorrhea seems to be broken up and menstruation proceeds normally thereafter

73 *Habitual Abortion in Connection with the Internal Secretions F Lehmann
74 Radical Operation for Prolapse of Genital Organs H Cramer

67 **Influence on Genital Sphere of Loss of Adrenals**—Novak studied this question on 166 rats, finding that the genital organs in young rats showed extreme changes after the adrenals on both sides had been removed, and the sexual functioning was correspondingly much reduced The atrophy and hypoplasia of the genital organs were more pronounced the younger the rat at the time the adrenals were removed

69 **Influence of a Pregnancy on Mortality from Tuberculosis**—Tussenbroek compares tabulated statistics fr Amsterdam and Rotterdam for various recent decades

showing, she says, that the mortality from tuberculosis among women is not increased by child-bearing. The fact that the woman is tuberculous is no reason for interrupting the pregnancy, according to the data here presented.

73. **Habitual Abortion and the Internal Secretions.**—Lehmann's extensive clinical and experimental research failed to establish any regular connection between habitual abortion and the internal secretions. Such was suggested, however, by the success of a course of treatment with potassium iodid and iron. It failed *only in one of the thirteen cases reported of* essential habitual premature delivery or miscarriage; that is, in women free from organic disease. The medication must be kept up systematically throughout the pregnancy, possibly varying the preparations and suspending all at intervals.

77. **Heart Disease and Pregnancy.**—Eisenbach states that some cardiac defect was noted in forty-five of the 3,037 obstetric cases at the Tübingen maternity in the last five years. The trouble was a valvular defect in thirty, and in the myocardium in thirteen, a total of 1.4 per cent. of all the deliveries. Twelve pages are devoted to categorical classification of the cases. As long as compensation was maintained the heart affection did not represent a serious danger. *Only when the valvular defect or myocardium injury was* especially severe were serious disturbances liable, also in all cases in which the heart disease was complicated with nephritis or chronic lung disease. The special type of valvular disease did not seem to affect the outcome, but if compensation becomes upset and internal measures fail to restore the balance, labor must be induced without delay. In the second half of pregnancy a vaginal incision in the uterus will enable it to be evacuated with the least strain on the patient. No special tendency to abortion was noticed and no special danger for the birth itself in a case of uncomplicated valvular defect. On the other hand, a damaged myocardium is liable to become totally incompetent even during the first stage of labor, when the labor contractions bring such sudden sharp changes in the circulation. This may occur when up to this point compensation had been maintained unimpaired. Operative delivery is thus indicated, as a rule, only when the myocardium is seriously impaired, and with danger of this kind, it is wiser to do some operation to protect the woman against future pregnancies.

General anesthesia is absolutely contra-indicated with severe weakness of the heart but it can be applied with compensated valvular defects and slight cardiac insufficiency. The mortality was 0.42 per cent. in 235 cases of delivery with heart disease, excluding those in which the fatality was due to other causes. The puerperium is not affected by the heart disease in any special way, but puerperal infection runs a peculiarly menacing course and is exceptionally dangerous on account of the tendency for endocarditis to recur at the time. The disturbances from heart disease on the whole are more serious and menacing the older the woman; in his cases there was no mortality under 25; 4 per cent. mortality between this and 35, and 26 per cent. over this.

78. **Bacteriology of Puerperal Infection.**—Von Hecker states that the blood was found sterile in 67 per cent. of 100 cases of puerperal fever and only 8.8 per cent. of these patients died, while 50 per cent. died of those with positive bacteriologic findings in the blood. Streptococci were found in 81.8 per cent. of the positive cases.

85 Eosinophil Cells in Sputum. (Zur Frage der lokalen Eosinophilie.) F. Wendenburg.

82-83. **Therapeutic Pneumothorax.**—Breccia writes from the medical clinic at Genoa in charge of Maragliano to discuss the history, nature and results of this method of compressing the tuberculous lung. He says that roentgenoscopy confirms the thorough obliteration of the cavity. He also discusses what *happens in the other lung at the same time, sound or* diseased. When the lung has been compressed in this way, the measure must be kept up until a clinical cure has been realized. The length of the period required for this varies with the extent and severity of the process, the condition of the pleura and the general health. The compression of the lung must be kept constant and regular, avoiding danger of overpressure and rapid expansion. About 100 c.c. of the gas is absorbed on an average in twenty-four hours; the quantity of the gas and pressure are less instructive than the space taken by the pneumothorax; this can be determined by the way in which the walls yield to pressure and by the retraction of the lung. The absorption of the gas proceeds most *rapidly the healthier the pleura, the more movable the lung* and the greater the muscular development. Mayer reviews what has been accomplished in this line by others and reports the details of eighteen cases of pleural effusion consecutive to artificial pneumothorax out of a total of forty-six cases in which he had applied the measure. The pleural effusion in different cases varies in the mechanism of its origin, its course, its composition and the influence on the health as a whole. The effusion may be tuberculous or represent acute infection or it may be the result of perforation of the pleura, but the most common type is that with *eosinophilia; this* latter group is the largest and it indicates a favorable outcome, especially when the tubercle bacilli disappear from the effusion. The effusion in these cases contains specific antibodies, such as are not to be found in the other types. This large antibody content has a favorable influence on the further course. The effusion of the three other kinds has an unfavorable influence, and the pleura should be drained or the fluid drawn and reinjected for autoserotherapy.

87. **Arthritis Sign of Infectious Process in Upper Air Passages.**—Menzer thinks that there is always some chronic infectious process somewhere in the upper air passages, tonsils, nasal sinuses, bronchial lymph-nodes, or possibly in the ear, which is responsible for the weakening of the organism and metastatic joint disease. The germs at work may be streptococci, pneumococci or even tubercle bacilli. From the hidden focus, on the occasion of "catching cold" or other injury, general infection results, with metastatic processes in joints, the heart or the serous membranes. They may develop slowly and insidiously or with an acute and stormy course. The insidious cases are generally referable to tubercle bacilli, and the whole trouble is liable to be favorably influenced by tuberculin. All treatment of joint disease should proceed on the assumption that the arthritis is merely one manifestation of a central infection. For this reason salicylic medication is not the proper treatment, as this at best merely relieves the symptoms in the joint without combating the central primary cause while it interferes with the natural production of antibodies and development of natural immunity. Treatment should aim to sustain the body in its struggle against the infection, with baths, hot compresses, vaccine therapy, a course of tuberculin treatment, etc. These will aid the organism to conquer its infection and the cure will be a permanent one, not the mere palliative relief afforded by salicylic medication or the like. He gives a number of case histories to illustrate his views and emphasize the folly of treating merely the joint symptoms while neglecting the underlying chronic infectious process. Persons with latent chronic infection of this kind generally show signs of anemia, a tendency to headache and palpitations; they sweat easily and catch cold readily, with frequent sore throats and catarrh of the upper air passages.

89. **Fluorescein Test of Kidney Functioning.**—Strauss says that reliable information can be obtained in regard to the functional capacity of the kidneys by giving the patient, fasting, 1 gm. of fluorescein-sodium in a cup of tea or cocoa in the morning, and then examining the urine voided at ten-minute intervals until it begins to show signs of fluorescence. After thirty hours the urine voided every hour or two is examined anew for signs of the fluorescein. In his experiments with thirty persons he found that the healthy passed distinctly fluorescent urine in from ten to twenty minutes after taking the drug, and that the fluorescence disappeared again after thirty-five or forty hours. At the beginning and close of the test he added a little ammonia to the urine as this rendered the fluorescence more pronounced. In most persons the complexion showed a slightly jaundiced tint, the more pronounced the less perfect the elimination of the drug in the urine. The drug used is the mother-substance of eosin, and as it is taken by the mouth instead of requiring subcutaneous injection, the technic is much simpler than with the usual tests.

November 28, XVII, No. 6, pp. 603-640. Last indexed Dec. 6, p. 2110

104 *Trauma and Tumor. W. Graef.

104. **Injury as a Causative Factor in Tumors.**—Graef has found 161 articles in recent literature bearing on this subject. It is particularly important in Germany on account of the advanced state of industrial insurance. The German cancer research society has recently begun to class all carcinomas and sarcomas under the heading of cancer, on account of Ehrlich's discovery that an inoculated carcinoma in mice was liable to develop into sarcoma in the course of several generations. But Thiem and others warn expressly against this as liable to lead to great confusion. Graef says in conclusion that one cannot be too skeptical in regard to the participation of trauma as the causative factor in a malignant tumor. Physicians are too apt to accept a causal connection between a trauma and development of a tumor later. The connection is most evident when a metastatic tumor develops at some unusual point as, for instance, in a case reported by Lubarsch in which a cancer developed in the forearm after injury of the arm at this point. Necropsy nine months later disclosed that the tumor was a metastasis of a carcinoma in the esophagus which had caused only two other metastatic tumors, minute nodules in the liver.

105. **Intravenous Nutrition.**—Rabbits and dogs were fed by intravenous injection of yolks of eggs in physiologic salt solution. Weight and nitrogen balance were maintained until the beginning of anaphylaxis, which occurred with rabbits on the fourth or fifth day, in dogs on the fourteenth. Several of the animals died from anaphylactic shock. After the beginning of the anaphylactic stage albumin metabolism was limited. Before that, albumin, fat and carbohydrates were utilized as in normal feeding. Schott concludes that the organism can assimilate food material given in this way and thrive on it. (Compare with editorial in THE JOURNAL, Nov. 22, 1913, p. 1908.)

106. **Effect of Calcium Salts on Kidney Function.**—Eisner tested the effect of calcium lactate on normal and diseased kidneys and found an improvement only in one case. In some cases there was no appreciable change, and in some cases there was decreased function. He reiterates in conclusion that a substance which tends to inhibit kidney function is not to be recommended for therapeutic use.

121 Simplified Electric Apparatus for Local Passive Exercise of the Muscles. (Ein einfacher Entfettungs- und Muskelübungsapparat.) Hergens.

112. **Treatment of Apoplexy.**—When the apoplexy is due to thrombosis of a vessel in the brain, venesection is directly contra-indicated; the patient already shows symptoms of lack of blood in the brain and treatment should aim to supply more blood to the brain, lowering the head, removing all constricting collars or bands, giving autotransfusion and, best of all, stimulants for the heart. The diagnosis of thrombosis in a typical case reported was based on the gradual oncoming of symptoms, signs of arteriosclerosis, defective heart action, and a history of a previous attack of thrombosis in the leg. The carotid pulse was weak, and the jugular veins showed alternately as grooves and then they protruded in turn. The skin of the face was cool, the peripheral portions and mucosa livid, and if we could look into the fundus of the eyes we would see the vessels contracted. This is the picture with thrombosis, exactly the reverse of that with

true apoplexy, from cerebral hemorrhage, in which hyperemia dominates the picture while with thrombosis it is the anemia At the same time, both have symptoms in common of pressure on the brain

With the thrombosis it is better to refrain from giving anything by the mouth as with the necessary constant reclining the danger of infection from aspirated foreign matter is particularly serious When the blood distends the vessel below the thrombus, leeches might be applied, but it is better to draw the blood away by cold packs to the feet, this leaves the blood still in the body Twitching of the limbs or certain muscles indicates irritation of the brain, or even constantly repeated movements not of spasmodic nature Sedatives are indicated here and small doses of morphin are generally effectual The room must be kept warm and the patient be placed to avoid danger of bedsores, and be kept absolutely quiet and free from external irritation No attempt should be made to treat the paralysis until the acute phase has passed

With embolism the aim of treatment is entirely different, everything must be done to keep the embolus where it is and prevent more from following Measures to increase the blood pressure are absolutely contra indicated, when the physician is at a loss to know which is the graver danger, the collapse in the circulation or the danger of new embolism, he must reflect that the heart has a large amount of reserve power while new embolism may prove fatal at once The head should be kept high and absolute quiet should be enforced If the head is much congested local blood letting may be required A cool foot bath will draw the blood away from the head Try to have the patient sleep Especially with heart disease causing dyspnea and a sense of oppression in the heart region, a little morphin may do great good, relieving the patient of his restlessness and dread The doses should not be over 0 01 or 0 005 gm Recent endocarditis or a valvular defect is generally responsible for the embolism The vessels below the embolus swell

With cerebral hemorrhage, measures to reduce the blood pressure are called for, the head and shoulders are raised, with hot foot baths or mustard packs for the feet, ice to the head, venesection, rectal enemas, with heart stimulants in case of actual collapse but not otherwise The first few days following a cerebral hemorrhage are full of danger, as the hemorrhage may recur, many patients succumb during the following week so that the greatest care is still necessary and absolute quiet must be enforced, keeping out the family No food, but cold drinks should be allowed, milk, sherbet, lemonade, carefully avoiding anything liable to be vomited on account of the danger of aspiration pneumonia After thorough evacuation of the bowels with enemas or a laxative if the condition permits, the bowels had better be kept quiet with tincture of opium, ten drops three times a day for a few days Paralysis of the bladder must be watched for Potassium iodid does not do any good nor operative measures unless trephining may be considered advisable in case of excessive pressure on the brain, but it will raise the blood pressure and thus increase the danger Neisser's technic for puncture of the brain might evacuate fluid blood if present, but it is liable to bring on hemorrhage anew Even with this danger it is safer than lumbar puncture

115 **Pneumococcus Influenza.**—Walb states that at Bonn during the last few years there have been numbers of cases of a febrile affection which seemed to be typical influenza, but for which the pneumococcus was responsible The lesions are in the nasopharynx and may involve the ear and the sinuses of the nose The influenza bacillus was never found in these cases In fact, Walb adds, the hygiene institute at Bonn has not encountered an influenza bacillus for ten years, and the hygiene institute at Berlin says the same

116 **Early Diagnosis of Tabes**—This communication from Rio states that tabes is common in Brazil but that it often is not correctly diagnosed and patients are treated for gastric ulcer, intestinal troubles, neurasthenia, etc, and the tabes left untreated This is the more serious as Austregesilo's experience has shown that vigorous treatment, as for severe syphilis, will arrest the tabes in many cases and cause marked improvement Neither race nor climate seems to have any influence on the frequency of tabes He lists the eight leading symptoms and says that any three of them confirm the diagnosis of tabes, one alone does not make tabes, but may indicate the pretabes stage

130 **Most Favorable Age for First Childbirth.**—Bondy and Marek recently wrote an article on this subject (*Ztschr f Geburt und Gynak*, LXIX) and Richter and v Hiess take up the discussion of it Their statements are based on 64,022 obstetric cases at the Vienna obstetrical clinic 1892 1911 Among these there were 26,091 primiparae who gave births to normal infants weighing more than 2 500 gm They conclude that the physiologic limits for the first birth are 17 to 26, and within these limits the optimum is between 18 and 23 During this time there are fewer complications for both mother and child This includes four more years for the physiologic limit and three more for the optimum period than Bondy and Marek accept At the ages 14 to 17 complications are more frequent and delivery more protracted on account of insufficient development of the uterine and pelvic musculature They also infer that the period from the twenty sixth to twenty ninth year is not especially unfavorable as the transition to the conditions observed in elderly primiparae takes place slowly and gradually In these two points also they differ from Bondy and Marek

131 **Pregnancy Four Years after Steam Cauterization of the Uterus**—Some years ago there was a lively discussion as to the value of introducing hot steam into the uterus as a treatment for hemorrhage, but not much has been heard of it lately Baumgart and Beneke here report a case which is a contribution to the solution of the question In 1907 a woman who had had three children was treated by atmocausis for hemorrhage from the uterus, and after that time had never menstruated In 1911 she was sent to the hospital with the diagnosis of impacted transverse presentation No fetal parts could be palpated, there was no heart sound and the patient had never felt any fetal movements An abdominal hysterectomy was performed The fetal parts could be palpated only with difficulty even after the abdomen was opened There was a cicatrix in the cervical canal that prevented normal delivery, undoubtedly due to the steam treatment The four years of amenorrhea followed by pregnancy testified that most of the uterine mucosa had been destroyed, so menstruation could not take place But a small area had been left intact, large enough to permit the embedding of the impregnated ovum The great objection to the steam treatment is that there is no possibility of measuring its effect on the mucous membrane of the uterus, and that it is very apt to lead to scar formation which interferes with future deliveries

139. **Rubber Ball Compression of Tuberculous Lung.**—Gwerder refers to cases in which adhesions prevent effectual compression by gas. Hitherto treatment has been restricted to detaching the lung—pneumolysis—hoping that it will fall in at the point of the cavity and thus effectually compress it, or to injection of a solid filling to fill up the space. If the lung tissue or cavity walls are tough, pneumolysis does not produce effectual compression, and if a solid filling is injected, it naturally, under the influence of gravity, pushes downward instead of laterally on the cavity. To obviate these objections, Gwerder introduces a light inflatable rubber ball inside the chest opposite the cavity, and by inflating the light ball exerts direct compression exactly at the point where it is required. Experiments on rabbits, cats and dogs showed that the ball is easily introduced, easily inflated as required and to the required amount, and the animals wore the balls for months without apparent injury. When its purpose was accomplished the ball was readily removed. As the wall of the cavity is the point of least mechanical resistance, the pressure from the inflated ball is strongest at this point. The excellent results in the experimental research justify, he is confident, the application of the rubber-ball compression in the clinic.

143. **Calcium Chlorid in Hay Fever.**—Emmerich and Loew report five cases in which a chronic tendency to hay fever was broken up and the patients permanently freed from its grip by continued treatment with calcium chlorid. The drug must be kept up for months, years, indefinitely, as it aims to remedy a constitutional defect—a disturbance, probably, in the functioning of the parathyroid bodies. They recommend all persons with a tendency to hay fever and even the healthy in regions poor in lime, or persons who do not take much milk or vegetables, to keep up the calcium chlorid indefinitely through years. Their experience of three and six years has confirmed, they say, the absolute harmlessness of the drug in the form advocated, while the general health is much improved, persons tire less readily, they require stimulants less, they sleep better, are less subject to infectious diseases, catarrhal affections, bronchitis, etc., the vital processes become less sluggish, and waste is thrown off more readily and completely. They add that Metchnikoff's favorable results with yoghurt are probably due to the lime in the milk. The dosage they advocate is a teaspoonful of a 20 per cent. solution of crystallized calcium chlorid in distilled water, to be taken in a quarter of a glass of water in the course of the three principal meals.

146. **Gold Reaction in Cerebrospinal Fluid.**—Eicke here reports the application of Lange's colloidal gold chlorid test to 323 patients, along with the other usual tests, the Nonne, the cell-count, the Wassermann test and quantitative estimation of the albumin. (Some experiences with the gold test and description of the technic were given in THE JOURNAL, July 5, 1913, p. 13.) Eicke's communication issues from Wechselmann's service at the Virchow hospital at Berlin, and certain slight modifications in Lange's original technic are described and advocated. The reaction occurs according to three types, that with normal fluid, that with syphilitic, and that with inflammatory processes other than syphilitic. With syphilis at the secondary stage the reaction occurs at a dilution of 1/25 up to 1/130, the maximum always being between 1/40 and 1/80, and the tint purple. With general paresis, the maximum runs from 1/10 to 1/640 and the color reaction is a white tint. With tuberculous meningitis the reaction does not begin till 1/320 and runs to 1/1280, tint purple; while with suppurative meningitis the reaction starts at about 1/160 and continues beyond 1/2560, the color reaction running through all the tints down to white and back again to violet. Necropsies in four cases of suppurative meningitis confirmed the findings with the gold test, as also in the 26 cases of tuberculous meningitis.

The reactions with the gold test were thus specific to a remarkable extent and extremely sensitive and reliable, a negative response to the test being obtained constantly in cases of cholera, circular insanity, dementia praecox, and arteriosclerotic dementia, in epilepsy, and in 23 cases of neurasthenia. Only one case of congenital syphilis is listed. The response was constantly positive with the specific type of reaction in the 26 cases of tuberculous meningitis and in all but two of the 24 tabetics and 54 paralytics. The test is particularly instructive in distinguishing between incipient general paresis and neurasthenic disturbances in a syphilitic. In both there may be lymphocytosis and positive Wassermann, but the negative gold reaction will exclude general paresis. The reaction is not so pronounced with tabes as with general paresis and resembles the ordinary syphilis type.

147. **Benign Albuminuria.**—Veil relates in detail the case of a young man with orthostatic albuminuria, especially pronounced when there was much intake of salt. The weight persisted unmodified by the retention of salt, and the blood kept normal. There was also a tendency to bradycardia and irregular respiration rate, with low blood-pressure and eosinophilia. The young man consulted numerous physicians and all had at first ascribed his albuminuria to nephritis and for months he had been kept in bed on an antinephritis diet. The course of the case finally revealed the disturbances to be a psychoneurosis accompanied by chronic albuminuria; treatment on this basis has produced good results. The phenomena observed link the psychoneurosis and the albuminuria: the psychosis, vagotony, orthostatic modification of the secretions, albuminuria and status thymolymphaticus. The mother has exophthalmic goiter, an uncle a psychosis, while father and grandfather are men of unusual talent. The case is an interesting example of the interplay between the organic manifestations of secretory disturbances and psychic anomalies. Every physician who examined him diagnosed nephritis and considered him psychically sound. Veil expatiates on the case as a warning against routine diagnoses. It is possible that the young man might have outgrown the tendency and developed into sounder health if it had not been for the restrictions imposed by the physicians who treated him on the assumption that he had chronic nephritis, with the consequent worry and dread on his part. Both the psychic organism and the physical suffered from the salt-poor diet and restrictions

and both benefited materially when all these were dropped and the patient was urged to lead a normal life and take up sports.

152. **Sensations During a Herniotomy Without an Anesthetic.**—Hartmann is 35 and healthy, and records his sensations as he had an operation done for umbilical hernia without any anesthetic or sedative. The peritoneum proved to be far less sensitive than he had expected. Only when the omentum was pulled he experienced intense pain close to the spine, the pain so severe that it stopped his breathing. The pain was also intense when the fascia was cut with scissors, the pain spreading to the left in a circle, the pain resembling that from an electric shock. The sensation was always in the left side, regardless of where the fascia was being cut. Suturing the fascia and tying the knots elicited similar pain but not so severe. The operation proper did not require so much traction and cutting as he insisted on to test the sensitiveness of the parts, and he thinks that with some will power anyone could stand even a major intraperitoneal operation without anesthesia. Particularly with operations on the appendix, he urges others to refrain from the use of anesthetics so as to study conditions in regard to the sensation of pain in the inflamed peritoneum.

153. **Prevention of Danger of Embolism with Injection of Paraffin.**—Hartung states that the danger of embolism is absolutely averted if the injection is made after the blood has been expelled from the region and the paraffin is allowed to harden before the constricting bandage is removed. The only indispensable condition is that the blood can be properly expelled from the part. This is simple and easy when the injection is to be made in a limb, and it can be managed also for the breast if it is not too firm, and also for the scrotum.

155. **Cornelius' Nerve Points and Swedish Massage.**—In the nervous and other patients with vague disturbances certain points may be tender on pressure, and pain may be induced in them by muscle traction and by fluctuations in the blood supply. Cornelius calls them nerve points (*Nervenpunkte*), and regards them as responsible for a number of disturbances, neurasthenia, hysteria, etc. Pressure on the nerve points does not always induce pain in them; the pain may deceptively radiate or jump to other points, possibly to the other side of the body. Cornelius explains these nerve points as the result of connective-tissue proliferation checking the passage of nerve impulses; this assumption is sustained by the fact that the nerve points can be restored by massage to normal condition, and the additional fact that these nerve points are particularly liable to develop in scar tissue. The nerve point is thus a spot where the functioning of the nerve fibers is mechanically impeded. Massage is done with circular kneading manipulations, and as one works in deeper he feels the tension of the muscle and the typical contraction. Swedish massage works along the same lines as Cornelius' massage of the nerve points, and the experiences with each throw light on the mechanism of the other. Port urges physicians generally to study and practice massage of the nerve points.

156. **Artificial Nose.**—Zinsser regards Hennig's idea of making an artificial nose from a soft material as a great advance in this line. He gives two illustrations "before and after," which confirm the excellent result obtainable. A plaster cast is made over a normal nose and melted gelatin, tinted a flesh tint, is poured into the cast. When it has hardened it is taken out of the cast, holes are made for the nostrils, and the edges are softened with a hot spatula. The artificial nose is then fitted over the patient's deformed nose, and is held in place with a little varnish or mucilage. The edges of the prothesis are made to run out into a thin sheet all around, and this sheet is patted down on the skin with a hot cloth, and a little powder dusted on the edges. Being comparatively plastic, the gelatin nose yields and moves with the play of the face, giving a particularly lifelike look to the new nose. The patients soon learn to make a new prothesis for themselves as needed. The whole procedure is extremely simple, the materials are very inexpensive and the cosmetic effect unusually good.

157. **"It Won't Hurt."**—Nassauer emphasizes the folly and mistake of telling a patient before some slight but needed minor operation that it will not hurt, when it does hurt. The patient is angry at the physician for fooling her and angry at the pain endured and he seldom or never sees her again in his office. It is far better to err on the other side and tell the patient that it will hurt when in fact it can scarcely cause any pain. She will be proud of her endurance when the pain proves less than she dreaded and her confidence in her doctor will increase.

163 *Apoplexy after Lumbar Puncture. G. E. Weinlander.
164 Typhoid Periostitis; Eleven Cases. H. Braza.

158. **Friction Sound as Early Sign of Perforation of Gastric Ulcer.**—Brenner calls attention to a metallic ringing rubbing sound behind, low down under the diaphragm, which he found constantly in five of six cases soon after the perforation. It is caused by the fluid stomach content, mixed with air, crowded between the diaphragm and the distended stomach. It is characteristic of perforation only in the first few hours thereafter.

159. **Dermatoses and Anacidity.**—Lier and Porges have been investigating gastro-intestinal functioning as a possible factor in skin affections, and found nothing to indicate any connection between them in a certain proportion of cases, but in others the connection seemed unmistakable. This was beyond question in four cases of recurring urticaria or furunculosis in which there was gastric anacidity. By administering hydrochloric acid regularly the skin affection was promptly cured. This result was particularly striking in the case of a woman of 30 and a man of 27 who had had for years severe urticaria constantly recurring, absolutely refractory to all therapeutic measures. The lack of the disinfecting action of the normal gastric juice caused abnormal digestive processes and production of toxins in the intestines, and these toxins evidently maintained the dermatosis. By supplying hydrochloric acid from without the digestion righted itself and the toxins were no longer produced in the same way. One of the patients had suffered merely from pruritus, coming on in waves; improvement was evident the day after commencing the hydrochloric acid—thirty drops a day of dilute hydrochloric acid after each of the three meals—and by the third day all tendency to pruritus had disappeared. Another of the patients had eczema and furuncles for ten or eleven months, rebellious to all treatment, but healing entirely within a week after the hydrochloric acid had been systematically taken.

163. **Apoplexy with Fatal Outcome after Lumbar Puncture in Uremia.**—A boy of 12 had acute nephritis with uremia and he died forty minutes after lumbar puncture. Hydrocephalus and various malformations evidently caused a predisposition. The heart kept beating after the boy stopped breathing, and it did not cease to beat for seventeen hours, during which time artificial respiration was kept up.

165 *Alcoholism in Children. C. Ortali.
166 *Prophylaxis of Plague by Bacteriologic Control of Rats. (La difesa contro la peste nel porto di Trieste ed in quello di Genova.) M. Gioseffi.
167 Cerebrospinal Meningitis in Children: Three Cases. E. Palmegiani.

165. **Alcoholism in Children.**—Ortali discusses both the injury from alcoholism in the parents and that from acquired alcoholism in children. He reiterates that a child procreated while one or both of the parents is drunk—even although the parents otherwise are only moderate drinkers—is usually below par in some way, mentally or physically, and refers to the reputation for physical and mental degeneracy borne by "holiday children." Even 1 per cent. of ethyl alcohol in the

water will check the development of the embryo; 2 per cent. will cause development of deformities and the growth is much retarded, while with 4 per cent. there is no growth at all. Alcohol taken as a beverage passes into the ovaries, testicles and prostate and into their secretions. Both ovum and spermatozoa suffer from the injurious effect from the alcohol, which is preeminently a poison for protoplasm. The statistics of criminology show plainly the influence of alcoholism in the parents as a deficiency in the moral sense is one of the commonest manifestations of an inherited taint from alcoholism. The offspring are unusually liable to abuse of alcohol as they grow up; he has investigated this in a number of cases and found a family history of alcoholism in habitual drunkards even although they were brought up entirely remote from their parents, so that the influence of example and training was out of the question. He reports a case of multiple cerebrospinal sclerosis in a young man whose parents had been hard drinkers, and for which no other cause could be assigned. The growth is frequently stunted in districts where there is much abuse of alcohol and the children of persons addicted to alcohol are peculiarly susceptible to tuberculosis. He also cites instances of the wasting away of infants nursing drinking mothers.

Acquired alcoholism in children causes more intense intoxication than in adults and the symptoms are manifested more predominantly in the nervous system; infants are liable to have convulsions but without fever or bowel trouble. When the alcoholism is chronic, the child is restless, grows very slowly and is liable to have insomnia, strabismus and gastrointestinal disturbances, finally wasting away completely. In older children the intoxication resembles more that in adults but there may also be epileptiform convulsions, actual collapse, delirium or maniacal excitement. Intoxication from wine is characterized more by gaiety and excitement, while brandy, etc., bring depression and torpor. In intoxication from liqueurs, absinthe, etc., the plantar reflexes and perception of pain are exaggerated, while they are deadened with ordinary alcohol intoxication.

166. **Prophylaxis of Plague.**—Gioseffi compares the experience at Trieste and at Genoa in regard to warding off plague. Several cases have occurred at various times at Trieste and one was reported there quite recently. When a case is declared, steps are taken to prevent the spread of the disease and no epidemic has resulted in any instance. At the same time, he thinks that the method of prophylaxis in vogue at Genoa is far more logical and is bound to be more effectual. At Genoa the rats are kept under bacteriologic control on board arriving vessels, on the docks and in the warehouses. By this means the infected rats are discovered in time to ward off any spread of the disease to man.

174 *Shall Gummatous Tumors in the Liver be Excised? (Sifilide gommoso del fegato.) G. Frattin.

174. **Operative Treatment of Gummatous Tumor in the Liver.**—The excellent results in the case reported confirm the advantages of resecting the tumor in the liver after failure of medical means to relieve. Even if the patient is known to be a syphilitic, the liver process may be of malignant or parasitic nature, while gummatous tumors in the liver are not much influenced by even vigorous antisyphilitic drugging, and one can seldom be absolutely sure that the trouble is actually a syphilitic process, especially when, as in the case described, the patient strenuously denies venereal infection at any time. Frattin reviews the experiences of others with operative treatment of rebellious gummatous tumors in the liver, the consensus of opinion being evidently in favor of a prompt operation. If the tumor should prove to be of malignant nature any delay may prove disastrous.

185 Findings in Cerebrospinal Fluid in Diabetes. C. B. Udaondo.

175. **Tuberculous Gastritis.**—On the basis of a clinical case reported in detail, Goyena draws the clinical picture of tuberculosis of the stomach and the treatment for it. The patient was a woman of 34 with pulmonary tuberculosis and symptoms on the part of the stomach which could be the result only of an ulcerative tuberculous process in the stomach. Under treatment the same as for an ordinary ulcer, the gastric trouble was much improved. Among the measures applied was Tripier's method of hot enemas repeated two or three times during the day. The advanced pulmonary tuberculosis in such cases places the question of operative treatment in another light from that with other forms of gastric ulcer. After eight years of comparative health symptoms on the part of the stomach returned again, this time taking the form of stenosis of the pylorus. During this long interval there had been no further signs of an ulcer but the digestion had never been quite normal. After the stenosis had developed, partial gastrectomy and gastro-enterostomy were the only means of relief.

178. **Cancer in Argentina.**—Roffo cites various statistics which show that the increase in the deaths from cancer in Argentina and in the number of patients treated is due merely to the facts that malignant disease is diagnosed with greater precision now than formerly and that immigration has increased to such an extent. He states that the number of foreigners at Buenos Aires is increasing in a most remarkable way, more than nearly half the population being foreign-born. Nearly twice as many foreign-born are treated in the public hospitals as native Argentinians. Many of the immigrants are at or soon reach the cancer age. Buenos Aires receives most of the foreign element and it is far in the van in regard to the frequency of cancer. With a population of 2,950,384 native born and 1,004,527 foreign born, there have been 58,400 deaths from cancer in the country in the last twelve years. The stomach or esophagus was the seat of the cancer in 20 per cent. each, the pylorus in over 15 per cent. Owing to the large adult male immigration, women are comparatively scarce, and the uterus figures as the seat of the cancer in only 4.03 per cent. In sixty-two cases of cancer of the stomach, twenty-three of the patients were under 40.

180. **Serotherapy of Tetanus.**—Penna reviews his experience with serotherapy in about a dozen cases of severe tetanus. He makes a practice of injecting the antitoxin into a vein once or twice during the twenty-four hours in a dose of not more than 100 c.c. at a time. The effects seem to be equally

good with these small doses as with larger ones. Whenever there are generalized symptoms the outlook may be regarded as threatening, and intravenous serotherapy should be pushed and kept up for two or three days even although the patient may be improving. When the condition does not show a gradual improvement the injections should be made oftener, repeating them every two hours.

182. **Vaccination Against Typhoid.**—Alfaro discusses what has been done in this country and in Europe in regard to vaccination against typhoid and relates his own experience with it in a dozen or more cases of already declared typhoid. This shows the necessity for injecting the vaccine at the earliest possible moment, in case of an epidemic, without waiting for absolute certainty.

200 Serous Meningitis as Cause of Obesity and Genital Dystrophy. T Schwartz
201 Connection between Eczema and Internal Diseases (Ekzem und innere Erkrankung) M Hirschberg.

186. **Isolated Defect in Ventricular Septum.**—Bertels thinks that the case he reports is the ninth on record in which this congenital deformity was the only one. The heart works extra hard to overcome the effects of the deformity. Several of the persons lived to middle life and some were employed in work that required considerable physical exertion

187 **Auscultation of the Arteries.**—Dehio has published several communications on this subject before, and here states that further time and experience have only confirmed his statements in regard to the instructive findings with auscultation of the arteries, as he shows in twelve clinical cases reported in detail in which there was a spontaneous sound with the pulsation in the femoral artery during diastole. The data cited show that this sound occurs when the arterial pressure and the filling of the artery during the diastole period drop so low that the artery wall becomes completely relaxed and sinks in. The discovery of the spontaneous sound therefore in the artery is a sign of abnormally low blood pressure and defective filling of the artery during diastole. The sound is most pronounced, naturally, in the arteries with wide lumen as the difference between the stretched and relaxed condition of the artery walls is widest in this case

188. **Heart Block.**—Five cases are described in detail and the vast importance of the newer methods of examination, especially sphygmography and electrocardiography are emphasized as having wrought a revolution in our knowledge of the pathology of the heart.

189. **Polyserositis.**—From study of the literature and of several cases of polyserositis in his own practice, Kieseritzky concludes that the multiple serositis may induce two sets of symptoms, two distinct syndromes. One is characterized by inflammation of several of the serous membranes, especially the pericardium and peritoneum, with the resulting disturbances which include besides the chronic inflammation, disturbances from impairment of the circulation. These disturbances in the circulation may be due to the heart itself or to local factors impeding the passage of blood through the parts. The other syndrome is that of a chronic isolated inflammation of the pericardium causing the sheets to adhere together, with disturbances in the circulation, mainly in the liver and portal system. In one of the three cases reported in detail the first symptoms, edema and ascites, had been noticed twenty-five years before, and the affection was diagnosed by a physician six years later. This patient was a merchant of 63; at the age of 31 he had had a protracted attack of acute articular rheumatism, The ascites had been tapped at the age of 45 and had been followed by a laparotomy. It had not required tapping afterward until nearly the end, and the general condition had kept bearable except for occasional attacks of dyspnea. It seems probable that the laparotomy had a favorable influence on the development of the affection. The omentum was found adherent and was separated; the patient was in circumstances which permitted his taking good care of himself and refraining from manual labor, but the fact that necropsy showed the myocardium to be sound was probably an important factor in the long survival.

190 **Deviation of Complement in Heart Disease.**—The serologic findings in fifty cases of heart disease and in eighteen with failing compensation are tabulated for comparison. The severer the heart affection the less the proportion of complement and lysin.

192. **Abdominal Pain with Scarlet Fever.**—Mey states that a man of 26 and a woman of 20 developed suddenly about the end of the third week of scarlet fever intense pain in the abdomen, coming on suddenly and increasing for two or three days and then continuing without intermission till the seventh or eighth day; then subsiding abruptly with the fever which had come on abruptly with the pain and had kept up with it. No tenderness was left and recovery was soon complete and permanent. The pain had nothing of a cramp or colic nature, but kept up day and night, uninfluenced by morphin. A peculiar feature of both cases was that the patients found relief only when lying prone most of the time. Both patients were previously healthy robust young people, and none of the viscera seemed especially tender. Mey thinks that the only explanation of the pain can be the assumption of scarlatinal inflammation of the lymph-nodes deep in the abdomen.

195. **Connection Between Gastro-Intestinal Disease and Diabetes.**—Dietrich has examined the gastric juice in all his forty cases of diabetes and found normal conditions only in 25 per cent. There was severe gastric catarrh or achlorhydria in 67.5 per cent., and this large proportion excludes a casual coincidence. In one case of mild diabetes a severe gastritis developed within a month after the first symptoms of the diabetes. He does not think that the diabetes can be the cause of the gastritis, but inclines to the view that the latter is responsible in some way for the development of the diabetes, and this view is confirmed by the benefit which followed lavage of the stomach. The sugar disappeared completely from the urine in three of the nine cases of diabetes in which he applied lavage without enforcing an antidiabetic diet. He believes that the gastro intestinal trouble can be transmitted to the pancreas, and that in all cases of diabetes the gastro intestinal tract should be carefully examined for pathologic conditions at any point; remedying them may improve conditions in the pancreas, and this in turn will improve the diabetes. At least the condition in the pancreas may be kept from growing any worse and thus the diabetes be kept stationary. There is much to indicate, he says, that more than one organ concerned in the metabolism of carbohydrates must be involved in the causation of diabetes, and that the pancreas is not the one to be affected first. In a certain proportion of cases the pancreas becomes diseased from the spread of inflammation in the duodenum.

197. **Familial Splenomegaly.**—Feiertag describes a family at Riga with nine members three of whom have very much enlarged spleens. He compares the findings in these cases with those in thirty one from the literature. No cause for the splenomegaly was known in his cases except that one of the patients had had rachitis

PRINCIPLES OF THE TREATMENT OF INFANTILE PARALYSIS

ROBERT W. LOVETT, M.D.

BOSTON

The question of the treatment of infantile paralysis *is in these days always before the medical profession* of the United States, because each summer since 1907 has left behind it hundreds and sometimes thousands of victims, and with our added experience and our facilities for clinical observation, unfortunately far greater than anywhere else in the world, our ideas of treatment have progressed and have become more defined. If the point of view advanced in this paper is that of an orthopedic surgeon, it is because in most bad cases the surgeon or the orthopedic surgeon is sooner or later consulted, and these two from seeing end-results are perhaps best equipped to judge of the efficiency of the various forms of the earlier treatment.

EARLY DIAGNOSIS IN RELATION TO TREATMENT

The diagnosis of the disease before the appearance of paralysis is constantly overlooked. This is a cause of dissatisfaction to the family and of mortification to the physician, but probably not of great moment to the patient, for even when a correct or a provisional diagnosis is made early it is doubtful if anything can be done to influence greatly the course of the affection. Flexner's [*] experiments with hexamethylenamin showed that it seemed to have some immunizing effect on monkeys, but that after infection had occurred it had no effect. Still, on the supposition that monkeys and children may not be affected in just the same way, and as the drug in moderation seems to be harmless, the early use of hexamethylenamin seems our best chance. Occasionally cases occur which suggest that it may have been useful. For example, in July, 1911, three children in one family were affected at intervals of three or four days with fever, prostration and gastro-intestinal disturbance. The diagnosis of the first case was made only after the second child was in the height of her attack and before the third was affected. The first child received no hexamethylenamin, the second had a little, and the third had large doses from the beginning. The first child was severely paralyzed from the waist down, the second had weakness of the legs and back for a few months, and the third had no muscular involvement. All were equally sick. Such an observation, of course, proves nothing, but in connection with the early history of other cases that I have analyzed has made me feel that the early use of hexamethylenamin is desirable in suspected cases.

TREATMENT OF THE ACUTE PHASE

Little time need be spent in discussing the general measures of rest, catharsis, light feeding and quiet, which are universally agreed on. If any criticism is to be made it is that children slightly affected are often allowed to be too active; but generally the patient is so ill at first and so tender after the attack that this matter takes care of itself.

In formulating the treatment of the acute attack and of the days following we have only to remember the pathology of the affection. It is essentially a hemorrhagic myelitis with a widely distributed accompanying meningitis. Such a condition obviously demands general quiet, freedom from excitement and activity, and recumbency for a period of days or weeks. Even in the slighter cases the lesion cannot be immediately recovered from, and the observations on monkeys have taught us that some of the muscular paralysis is due to an edema in the cord accompanying the hemorrhagic process. The need of the measures spoken of must be self-evident, and my own practice has been to secure for even the slightest cases quiet for at least two or three weeks, and for the severer cases quiet until all tenderness has disappeared.

It must be said, however, that comparison of different treatments must be made with care, for no two cases are alike, the dose of poison or the individual resistance varies enormously, and the condition in the acute attack gives no very accurate means of telling what the ultimate outcome will be, except that the general conclusion may be formulated that on the whole very severe attacks are most often accompanied by severe paralysis and slighter attacks by more moderate and slighter forms.[1]

Two hundred and thirty-four cases of paralysis occurring in Massachusetts in 1907 were investigated in 1911 by a competent orthopedic surgeon.[2] Seeing as many of the patients as could be traced, he found that 25 per cent. had wholly recovered without regard to whether they had or had not been treated, and, moreover, that the analysis of the early history of these cases showed them to be average cases and that they could not in the early stage have been picked as cases in which the patients were especially likely to recover.

All of this goes to confirm the statement that the outcome of the case is not wholly determined by the treatment received, a point which parents are slow to grasp.

TREATMENT OF THE TENDER CONVALESCENT PHASE

Any rigid division of the disease into stages is misleading and out of accord with facts, because one stage melts into another so gradually that a dividing line is impossible. Still there are different aspects of the affection, which have been spoken of here as phases.

---

Following the subsidence of fever the patient is generally paralyzed in one or more limbs, tender to the touch and on motion, somewhat prostrated, and generally shows the results of a general infection. The latter, however, is soon recovered from, although in the severer cases the patient is generally below par for some time. This is the period when spontaneous improvement will begin, and the family may be assured that improvement which they can see will occur in a few weeks. It is generally difficult to make the family and the practitioner who has not had much experience in the disease understand that the best treatment at this stage is to let the patient alone except for preventing contraction of the Achilles tendon, which may occur to a troublesome extent in the first two or three weeks.

So long as tenderness lasts it may be accepted as evidence of the existence of some degree of active myelitis around the motor and especially the sensory centers of the cord. Under these condition it seems unphysiologic to stimulate by passive movements, massage or electricity the peripheral parts connected with those centers. Yet the early use of these measures is a common practice.

The tenderness may last from two to three months after the attack, and a perfectly inactive treatment is hard to pursue when the family has heard of the wonders of electricity and massage, and is anxious not to lose time. But so long as the tenderness lasts, the best practice is to let the patient alone so far as active treatment goes. Frequent changes of position are desirable, and there is no objection to the sitting position for the convalescent, to outdoor air, or to immersion in a warm bath with whatever active movement under water may be accomplished without discomfort.

There is no danger that the joints will stiffen, and in the first weeks the only troublesome complication to be feared, as has been said, is contraction of the Achilles tendon. If this is occurring it is justifiable to stretch the posterior muscles gently with the hand, even at the risk of causing some discomfort, rather than to allow a permanent contraction to occur. The easiest means of preventing the contraction is from the beginning to have the soles of the feet rest against a box covered with a blanket placed against the bottom of the bed, which holds the feet at a right angle to the legs. Unless this is done the weight of the bed-clothes and the dropped position of the unsupported foot in sitting will in most cases cause some degree of talipes equinus. The frequency with which this complication is seen in practice shows that it is not an imaginary danger.

TREATMENT OF THE CONVALESCENT PHASE AFTER TENDERNESS HAS GONE

With the disappearance of tenderness the time for active treatment has begun, and the sooner the patient is put on his feet and resumes activity the better. It seems probable on general principles that in cases of any degree of severity, even if tenderness disappears earlier than four weeks, active treatment should not be begun before that time, while some authorities would forbid active measures before the expiration of six weeks from the onset. In my experience, however, I have seen nothing but good come from instituting treatment at four weeks when the disappearance of tenderness has warranted it. The general condition of the patient, moreover, must not be neglected, as many of the children at this time have not wholly recovered from the effects of the infection, and are anemic, poorly, and easily fatigued.

The therapeutic measures at our disposal are massage, electricity and muscle training.

Massage may be expected to improve the local and general circulation, to facilitate the flow of lymph, and to retard muscular deterioration. It cannot, however, be expected to facilitate the transmission of a motor impulse from the brain to the affected or weakened muscle. In estimating its value in the treatment we must remember that it is only a part of the treatment.

Electricity is less highly regarded in the treatment than was formerly the case. The unintelligent use of electricity month after month to the exclusion of other measures has been one of the handicaps which has stood in the way of the best progress in many cases. It is quite possible that it may improve the muscular condition, and it may induce the contraction of muscles which cannot be reached otherwise, but its value has apparently been overrated, and in my own practice I have seen no convincing evidence that its use was beneficial, and I have preferred to concentrate on the measures which I could see were of distinct use.

Muscle training is apparently the most useful of the three therapeutic measures mentioned, apparently because it rests on the best physiologic basis. This is what happened before the attack, and what we want to have happen again, when the child desires to contract a certain muscle, to perform a certain motion: An impulse to move the muscle started from the motor area in the brain, and descended along the spinal cord motor-tracts to the spinal center controlling that muscle, where it was modified and distributed to the proper motor nerves and sent along them to cause muscular contraction. By the disease, certain spinal motor centers were destroyed, and can therefore no longer act to distribute motor impulses to their muscles. But such spinal centers and their connections are complicated affairs, and every muscle is connected with several centers, every center sends impulses to more than one muscle, and, moreover, the connections between the spinal centers are many. Unless, therefore, the destruction in the cord has been a very extensive one it is likely that some of the motor centers in any one region will have escaped destruction, and that it may be possible to establish new connections around the destroyed centers. If a railway wreck occurs on the main line and the track is blocked it is often possible to send trains by means of a branch line around the obstruction, so that service between the terminals is maintained. In the same way after a wreck of certain nerve centers it may be possible by a modified route to send a motor impulse from brain to muscle. On this principle of establishing new connections and opening new paths rests most of the claim of muscle training, but not entirely on this, because on account of the local edema of the cord accompanying the infiltration and hemorrhagic process certain motor centers are temporarily put out of order but not destroyed. Muscle training aids these to recover function.

Muscle training in its most obvious form consists in aiding the patient to perform a certain movement with the hope of stimulating an impulse from the brain to the weakened or paralyzed muscles. If, for instance, the dorsal flexors of the foot do not act, through being stretched, weakened, partly paralyzed or wholly paralyzed, in the exercise the foot is dorsally flexed with the hand and the patient directed to assist. If there is any muscular response less and less aid is given to the muscle by the hand, and it may be that in this way it can be trained to perform its function. A detailed account of the exercises for the different groups of muscles has been given by Wright.[3]

In my personal experience the success of muscle training and other measures has been greater in the legs than in the arms.

Another and equally useful form of muscle training consists in getting the patient on his feet at the earliest possible moment in order to call forth the instinctive muscular actions induced by the efforts to walk and balance. Even before it is possible to make much progress in this way, sitting is useful for the spinal and trunk muscles.

THE USE OF APPARATUS AND BRACES

Many patients at the beginning are unable to stand without apparatus, because, for example, the knees flex on account of weakness or paralysis of the quadriceps muscle. In these cases a caliper splint should be applied to hold the knees straight.[4] If the feet roll in or out varus or valgus braces should be applied. If the spine or abdomen is involved, a corset or jacket should be worn. Crutches are at first necessary in cases of paralysis of both legs. In other words, if the standing position induces malposition, such malposition must be corrected, because nothing but harm can come of it.

The fear that the early use of apparatus will promote muscular atrophy is wholly unreasonable, because nothing is so bad as disuse, and braces should mean the upright position, and the upright position means more muscular activity. The best way to avoid wearing a brace permanently is to put it on early and keep it on as long as necessary. For a growing child to walk about with a malposition is to bid for a permanent deformity.

DEFORMITY

If fixed deformity exists, it must be removed before treatment of any sort can be satisfactory. By fixed deformity is meant a condition in which the functions of a joint are limited, in which its arc is restricted. If a child sits with the foot dropped and it can be normally flexed by the hand to its normal extent it is merely a malposition; if it cannot be brought to a right angle it is a deformity. The difference is an important practical one.

The common and most troublesome deformities in neglected cases are fixed contractions of the feet in varus, valgus or equinus, flexion of the knees and contraction of the fascia lata, causing contraction of the thighs on the body. These deformities are easily remedied by stretching or cutting, and this is an essential preliminary to other mechanical or operative treatment. One should, however, be careful about cutting the Achilles tendon without some further operation when the anterior leg muscles are paralyzed, as an unsatisfactory limp and powerless foot may result.

The most troublesome deformity of all is lateral curvature of the spine, which occurs to some degree in most cases in which the shoulder, back or respiratory muscles are involved, which should always be watched for. Many errors would be avoided if every child with infantile paralysis were stripped and examined for scoliosis. It is singularly resistant to treatment, and when it affects the cervicodorsal region is practically not to be controlled. Lower down in the spine it may be greatly benefited by proper jackets and exercises. But such jackets must be applied early and worn persistently, because the cause, the unilateral muscular paralysis, is always present to aggravate the condition.

OPERATIVE TREATMENT

It is my purpose in this paper to give only the briefest possible outline of operative treatment. Operations are undertaken:

1. To correct fixed deformity.
2. To improve muscular function.
3. To secure stability of useless joints.

1. The correction of fixed deformity has already been dealt with.

2. The improvement of muscular function is accomplished by the transference of the tendinous end of a sound muscle to the place of insertion of a paralyzed muscle, so that its function is substituted for the lost function. The operation is useful in carefully selected cases, and must rest on careful anatomic study. The technic is of great importance, and has been fully discussed.[5]

The operation should not be performed until two or three years after the acute attack, and is not suitable for very young children. The passage of a considerable length of time since the attack is not a barrier to operation, and it is useful in adults.

The most important recent additions to our knowledge are that insertion into bone or periosteum (preferably the former) is preferable to insertion into tendons, and that silk elongation of the tendon may be performed with impunity and makes the operation much more widely applicable. Good function in the operated limb cannot be expected under six months.

3. The stability of flail and useless joints may be secured in several ways.

Arthrodesis, or the production of artificial ankylosis, in such a joint is obtained by opening the joint and removing the articular cartilage. In the ankle it has been most used, and under proper conditions furnishes a stiff ankle so that the patient need not wear a brace. It is, however, not to be done unreservedly. There is no use in stiffening an ankle unless the knee is good and can bear weight, and it is not to be done in children under 12, or a serious deformity may follow, incident to the growth of the foot, which may cause a bad varus. Arthrodesis of the knee should never be attempted in children on account of the danger of interfering with epiphyseal growth, and most adults prefer a brace which can be unlocked for bending when sitting down, to a permanently stiff leg. At the hip it is an operation little used, and chiefly to be considered when the hip is dislocated and can be reduced. In the shoulder it is sometimes useful.

Silk ligaments at the anterior aspect of the ankle are much to be preferred to arthrodesis in cases of flail ankle, because they do not cause a stiff joint, but allow dorsal flexion while they check plantar flexion or dropping of the foot; they do not cause bony distortion, and they may be safely used in middle childhood. Just as the silk elongation of a muscle is coated with fibrous tissue and becomes a tendon, so does silk inserted to check joint motion become coated with fibrous tissue to form a ligament.

In the technic one or two matters are of much importance. The crest of the tibia above the ankle is exposed. periosteum incised and turned back, and a hole drilled in the bone. One of the bones in the tarsus at the inner or outer side of the foot, or both, as the indication for support determines, is drilled in the same way, and one or two strands of heavy silk are passed through the tibial hole under the annular ligament, through the tarsal hole, and tied. The knot must come in the upper wound, as otherwise it is likely to chafe through from pressure of the boot. At least three months' support is necessary, and probably more.

[5] Lange, F.: The Orthopedic Treatment of Infantile Paralysis, Am. Jour. Orthop. Surg., August, 1910; Ergebnisse der Chirurgie und Pathologie, Payr and Küttner, Berlin, 1911, ii, 1.

The application of silk ligaments to other joints has not been fully worked out. In my own practice I have not done an arthrodesis of the ankle for dropped foot for several years, because the results of the silk ligament operation are so much more satisfactory. Other operations for fixation are advocated.[6]

In cases of paralytic calcaneus deformity, the Whitman operation[7] consists in removing the astragalus and setting the foot back in relation to the leg. After the operation the foot should be placed in the equinus position.

CONCLUSION

The foregoing seems to me to be a summary of the modern treatment of infantile paralysis, colored of course by my own personal experience. I think that those of us who live in communities which have been severely affected become every year more hopeful and more persistent in our efforts. There seems no time limit as to improvement, and many of the most neglected cases seem the most striking when they come to proper treatment. I have merely tried to show that a treatment based on our more recent knowledge of the disease differs in some respects from our former ideas, which were based on smaller experience and a less exact pathology.

THE MECHANISM OF RECOVERY IN PNEUMONIA

WITH SPECIAL REFERENCE TO THE CRISIS

LUDVIG HEKTOEN, M.D.
CHICAGO

In many acute infectious diseases convalescence often sets in abruptly. Within a few hours the temperature may fall several degrees, and forthwith there is a marked improvement in all the symptoms. This sudden change for the better is known as the crisis. Pneumonia, erysipelas, measles, the varioloid diseases and recurrent fever are diseases in which recovery or improvement frequently occurs by crisis.

In lobar pneumonia the crisis is a most characteristic phenomenon. Here it may take place with a suddenness without parallel in other disorders. In somewhat more than one-half of the cases "after the symptoms have lasted some five to eight days, less frequently a longer or shorter time, while at a constant height or even while increasing in severity, there is a rapid fall in the temperature with copious perspiration and rapid improvement in all the symptoms."

This abrupt change "from a state of extreme hazard and distress to one of safety and comfort" has excited interest and speculation in regard to its nature and mechanism since long ago. The early explanations are connected with the doctrine of critical days, a pet dogma of the galenic system, and appear to us as fanciful and of only historical interest. To attempt a brief review and summary of what is actually known of the reactions that occur at the time of crisis in pneumonia may be of interest, especially as it necessarily involves some discussion of recent advances in investigation concerning the specific cause and treatment of this dreaded disease.

MECHANISM OF HEALING AND IMMUNITY IN PNEUMOCOCCUS INFECTION

Soon after the discovery by Fraenkel and others that typical lobar pneumonia is caused by the micro-organism now commonly called the pneumococcus, G. and F. Klemperer[1] demonstrated that one can immunize animals against pneumococci, and that the blood-serum of such animals may have preventive and even curative powers with respect to pneumococcus infection. This is the starting-point of investigations of an immunologic nature the object of which has been to obtain an insight into the nature of the crisis and the cure of pneumonia.

The Klemperers explained the crisis as the result of a rapid detoxication due to the antidotal action of substances similar to diphtheria antitoxin, but as no one has succeeded in showing that pneumococci produce true toxins with antigenic powers like diphtheria and tetanus toxins, this idea that the cure of pneumonia is the effect of a direct antitoxic action remains without experimental support.

The antitoxic hypothesis was abandoned, and eventually the attention of investigators became focused on reactions which are antimicrobic rather than antitoxic: that is, which cause destruction of the invading microbes and thereby put an end to the processes that are responsible for the disturbances caused by the infection. This destruction is accomplished in some cases principally by direct solution or lysis and in other cases principally by intracellular, that is, phagocytic action, both being essentially digestive processes. In certain infections, notably the streptococcal and the pneumococcal, the phagocytic reaction appears to predominate.

In 1897 Mennes[2] discovered that the serum of animals immunized against pneumococci contain substances that in some way promote phagocytosis of virulent pneumococci which resist the phagocytes in the presence of normal serum. This very important observation did not attract the notice it merited, and it was not until some years later when Wright[3] described the opsonins and when Neufeld[4] quite independently discovered the bacteriotropins that the study of the mechanism of healing and immunity in pneumonia received a new impetus which still is effective and fruitful.

Wright gave the name of "opsonins" to substances in normal serum that attach themselves to bacteria and thereby render them susceptible to phagocytosis, and Neufeld applied the term "bacteriotropins" to substances with like action in the serum of immunized animals. There appears to be no fundamental difference between the opsonins and the bacteriotropins. Both are specific; that is to say, normal serum contains a variety of opsonic substances, each of which is specific for a given bacterium, and in immune serum the specific opsonic substance for the particular bacterium or cell with which immunization has been produced is developed in high degree. Both owe their full effect to the interaction of two substances, one of which is destroyed on heating the serum to 58 C. (136.4 F.) for thirty minutes, while the other substance remains unaffected. The latter is opsonic by itself, but its action is enhanced by the heat-sensitive element, and it is the heat-resistant element which is produced anew and specifically by experimental immunization or as the outcome of spontaneous infections.

[4] Neufeld and Rimpau: Deutsch. med. Wchnschr., 1904, xxx, 1458.

Whether we call these substances opsonins or bacteriotropins is perhaps a matter of taste, but in English literature custom favors the use of opsonins, although writers occasionally, and incorrectly, speak of bacteriotropins as different and distinct from opsonins.

While pneumococci of a low grade of virulence, and hence susceptible to the opsonic action of normal serum, in the test-tube experiment grow freely in normal serum and also in suspensions of washed leukocytes in salt solution, they are destroyed within the leukocytes in mixtures of washed leukocytes and fresh serum. This is readily demonstrable by means of plate cultures made at proper intervals with fixed quantities of such mixtures, and, other things being equal, the greater the number of leukocytes the greater the destruction of pneumococci which undergo solution or digestion within the cells.

Highly virulent strains of pneumococci resist phagocytosis under these circumstances apparently by virtue of containing a peculiar substance, discovered by Rosenow[5] and called virulin, which being readily soluble in salt solution may be extracted from the bodies of such pneumococci by soaking them in the solution.

As stated, however, immune serum may subject virulent pneumococci to phagocytosis, and such serum may protect susceptible animals against multiples of the fatal dose of pneumococci and even cure an established pneumococcus infection. Here an important reservation is to be noted: Neufeld[6] and others find that not all cultures of pneumococci respond in this way to the action of an immune serum prepared with the aid of a particular strain. Some strains will resist while others do not. Hence pneumococci as they exist in nature are not all alike in their biologic reactions, but *fall into separate groups.*

The recent work of Rosenow[7] shows that these groups do not necessarily represent absolutely fixed types, as they are subject under experimental conditions to radical changes and intermutations. The occurrence, however, under natural conditions of groups of pneumococci that for the time being at least have nothing in common so far as their reactions of immunity are concerned, is of the greatest interest because of its bearing on specific therapy and other problems of pneumonia.

Dochez and Gillespie[8] find that the pneumococci from cases of pneumonia form four distinct groups according to their immunity reactions. The agglutination test gives the same grouping as the much more difficult protection test, and Cole,[9] using agglutination to determine promptly to which group the pneumococcus in the individual case belongs, has obtained really promising results with the strictly specific serum. At present this is the most rational and hopeful basis we have for the development of an effective serum treatment of pneumonia.

The fact that pneumococci form separate groups is possibly of interest also in connection with repeated attacks of pneumonia at short intervals. These are now ascribed to an inadequate or too brief an immunity, but they may be caused at least in some instances by infections with strains of pneumococci that are not subject to the same immunity.

Returning now to the crisis and cure of pneumonia, we have to consider especially three factors, namely, the pneumococci, the leukocytes and the opsonic and protective elements in the blood.

VIRULENCE OF PNEUMOCOCCUS AT CRISIS

Is there a sudden loss of virulence in the infecting pneumococcus at the time of crisis?

Fraenkel and others concluded from results of inoculation of animals with pneumonic sputum, or with pneumococci isolated from the blood of animals inoculated with pneumonic sputum, that there is a definite fall in virulence shortly after the crisis, and it has been suggested that in cases in which there is recovery by lysis, the loss of virulence is more gradual and like the fall of the temperature in such cases. The methods used by these experimenters are not quite satisfactory. Thus the number of pneumococci in the sputum varies from time to time and especially after crisis. It is consequently not surprising that others obtained contrary results.

Graham[10] studied the phagocytability of pneumococci isolated directly from the sputum of pneumonic patients, but obtained no signs of any increase or decrease of virulence of the sputum organisms in the course of the disease. Theoretically, this method would seem serviceable, because avirulent pneumococci are readily phagocytable, while virulent ones resist phagocytosis in the presence of normal human serum. There is, of course, the possibility that even a brief sojourn in the sputum may reduce the virulence, and Leutscher[11] did find that the saliva has an attenuating influence on the pneumococcus. Leutscher made elaborate tests on animals of the virulence of pneumococci from the sputum in pneumonia, but did not obtain evidence of any sudden drop that might account for the crisis. His results indicate that so long as pneumococci are coughed up from the lungs they retain their original virulence.

We may conclude then that so far as the results of the work on pneumococcus in the sputum go, there is no evidence that the crisis in pneumonia is due to a crisis in virulence.

Nor is there any evidence that the pneumococci in the blood and in the lungs in pneumonia suddenly lose virulence at the time of crisis; whenever isolated during life from these sources they appear to have a high degree of virulence.

The indications are that pneumococci occur in the circulating blood in every case of lobar *pneumonia,* at least in the earlier stages in the cases in which there is recovery, and in increasing numbers in the cases that proceed rapidly to a fatal end. At the time of crisis the blood is sterile in the majority of the cases, but in cases with complications and delayed resolution, *blood-*

cultures not infrequently yield pneumococci that are virulent; only occasionally are pneumococci found in the blood after crisis for a short time in cases running a normal course.

Studying the exudate as obtained by puncture of the lung during life, Rosenow[12] found disintegrating pneumococci both within and outside the leukocytes, especially in the latter stages of the attack. In the early stages living pneumococci were always present, and in fatal cases in large numbers throughout the attack. In the patients who recovered by crisis, the number of cocci fell, sometimes abruptly, as crisis was approached, and when the blood had become sterile the exudate was also sterile.

All things considered, we must conclude that crisis does not mark a point at which the invading pneumococci suddenly become avirulent, but rather the point at which a more or less complete and rapid destruction of the organisms is accomplished.

THE LEUKOCYTES IN PNEUMONIA

That the leukocytes constitute an integral factor in the defensive mechanism of the body against the pneumococcus must be accepted as settled. Their behavior in pneumonia with regard to the crisis is significant. In favorable cases a marked leukocytosis appears early and disappears with the crisis, the fall being a little later than the fall in the temperature, especially when there is delay in resolution. Clinicians see in a falling leukocytosis without crisis, and in the absence of leukocytosis, a bad omen and indications of failing resistance and overwhelming infection.

The phagocytic and destructive powers of leukocytes appear to vary under different conditions. In certain acute infections with leukocytosis there is a non-specific increase in phagocytic activity when the outlook seems favorable, perhaps because of a preponderance of young cells. In pneumonia the leukocytes may be more resistant to heat than normally, have more attraction for pneumococci, and even take up pneumococci that rebuff normal leukocytes (Rosenow). Tunnicliff[13] found that in mild cases of pneumonia the leukocytic activity as a rule is above normal, while in severe cases it may be subnormal at the height of the disturbance, rising above normal as improvement sets in.[14]

Even if the leukocytic activity remained unchanged, there still would be a marked increase in the destructive power of the blood, other things being equal, because of the great increase in the number of the leukocytes.

As the pneumonic exudate begins to disintegrate, intraleukocytic ferments and other substances are set free that in all probability are pneumococcidal and no doubt contribute to the destruction of the free pneumococci, many of which, when examined in smears, seem to be in process of solution. But crisis can hardly be wholly dependent on resolution, because, while they usually concur, the crisis may precede resolution.
